

**APPROPRIATENESS OF INDICATIONS FOR
DIAGNOSTIC UPPER GASTROINTESTINAL
ENDOSCOPY AND PROPOSING GUIDELINES
FOR EVALUATION OF DYSPEPSIA**

Dissertation submitted for

D.M. BRANCH – IV

MEDICAL GASTROENTEROLOGY

THE TAMIL NADU DR. M.G.R. MEDICAL UNIVERSITY,
CHENNAI, TAMIL NADU

FEBRUARY 2006

CERTIFICATE

This is to certify that this dissertation on “**APPROPRIATENESS OF INDICATIONS FOR DIAGNOSTIC UPPER GASTROINTESTINAL ENDOSCOPY AND PROPOSING GUIDELINES FOR EVALUATION OF DYSPEPSIA**” is a bonafide work done by **Dr. B. SUMATHI** under my guidance and supervision, appearing for D.M. Branch IV Medical Gastroenterology in February 2006.

Dr. V. JAYANTHI, M.D., D.M.,

Head of the Department,

Medical Gastroenterology,

Govt. Stanley Medical College & Hospital,

Chennai - 600 001.

Dr. T. RAVEENDRAN M.D.,D.T.C.D.

DEAN

Govt. Stanley Medical College

& Hospital,

Chennai – 600 001.

Place :

Date :

DECLARATION

I, Dr. B. Sumathi, solemnly declare that the dissertation titled **“APPROPRIATENESS OF INDICATIONS FOR DIAGNOSTIC UPPER GASTROINTESTINAL ENDOSCOPY AND PROPOSING GUIDELINES FOR EVALUATION OF DYSPEPSIA”** was done by me at Govt. Stanley Medical College & Hospital during the academic year 2003 – 2006 under the guidance and supervision of my chief, **Prof. V. JAYANTHI. M.D., D.M.**

This dissertation is submitted to the Tamil Nadu Dr. M. G. R. Medical University towards the partial fulfilment of requirement for the award of D.M. Degree Branch IV in Medical Gastroenterology.

Place :

Date :

Dr. B. SUMATHI

ACKNOWLEDGEMENT

I owe my thanks to the Dean, Govt. Stanley Medical College and Hospital, **Dr. T. RAVEENDRAN, M.D., D.T.C.D.**, for allowing me to avail the facilities needed for my dissertation work.

I express my sincere gratitude to my **Prof. V. JAYANTHI, M.D., D.M.**, Head of the Department of Medical Gastroenterology, Govt. Stanley Medical College & Hospital, Chennai for her valuable guidance, constant support, supervision, co-operation and help in every stage of the study which has made this dissertation work possible.

My sincere thanks to **Dr. A. MURALI M.D., D.M.**, Asst. Professor, Department of Medical Gastroenterology, Govt. Stanley Medical College & Hospital, Chennai for his valuable guidance.

I am thankful to **Dr. T. RAJKUMAR SOLOMON M.D., D.M.**, Asst. Professor, Department of Medical Gastroenterology, Govt. Stanley Medical College & Hospital, Chennai for his valuable support.

I am grateful to **Dr. M. S. REVATHI M.D., D.M.**, Asst. Professor, Department of Medical Gastroenterology, Govt. Stanley Medical College & Hospital, Chennai for her assistance, support and constant encouragement.

I am thankful to **Dr. K. CAROLINE SELVI M.D., D.M.**, Asst. Professor, Department of Medical Gastroenterology, Govt. Stanley Medical College & Hospital, Chennai for her constant support and assistance.

I express my thanks to Mr. VENGATESAN, M.Sc., PGDCA., CCE., Lecturer in Statistics, Clinical epidemiology Unit for helping in Statistical analysis.

I am also thankful to Staffs of the endoscopic unit: Ms. K. Prema and Ms. M. Dhanalakshmi, Mr. K. R. Srinivasan for their assistance rendered.

Last but not the least, I express my sincere thanks to all the patients for their kind co-operation, without whom this study could not have been undertaken and to all my colleagues who shared their knowledge about the study.

**APPROPRIATENESS OF INDICATIONS FOR
DIAGNOSTIC UPPER GASTROINTESTINAL**

ENDOSCOPY AND PROPOSING GUIDELINES FOR EVALUATION OF DYSPEPSIA

INTRODUCTION

The term dyspepsia is used variably by health professionals to refer to a heterogeneous group of upper abdominal symptoms that may arise from numerous causes.¹ Patients seldom use the term dyspepsia and describe their abdominal symptoms instead in terms of discomfort, pain, bloating, fullness, burning, or indigestion. The way a patient perceives and reports these symptoms is dependent upon a complex interplay of biologic variables, personality traits, social support mechanisms, coping strategies, culture and language.

Dyspepsia is a common symptom in the community and more than one third experience the problem of indigestion in 6 months. Gastrointestinal (GI) disorders account for about 10% of all consultation with general practitioner and about half of them have dyspepsia.² Despite the substantial decline in the prevalence of peptic ulceration over the past 20 years, the incidence of dyspepsia has remained constant. It poses a diagnostic & therapeutic challenge to the clinician.

During the past two decades, the number of upper gastrointestinal endoscopy (UGIE) being performed has increased. This has resulted in long waiting list in many centers. The introduction of increasingly complex technologies in health sector makes it necessary to evaluate the procedures not only in terms of efficacy and cost, but also with regards to the appropriation of the procedure in clinical setting.³

For endoscopy services to be used to the best advantage only those patients for whom the procedure is appropriate should be referred. A joint committee of the Royal College of Physicians of London, Royal College of Surgeons of England, Royal College of Anaesthetists, Association of Surgeons, the British Society of Gastroenterology, and the Thoracic Society of Great Britain has been auditing gastrointestinal endoscopy in England. On the recommendations of that committee a working party was set up to determine the appropriate indications for endoscopy.

BACKGROUND

The British society has laid guidelines for an early endoscopy in dyspeptic patients with alarm symptoms and for those above the age of 45. Open access endoscopy is being currently resulting in high workload in endoscopy suite. There are no standard guidelines for performing UGI endoscopy in our population. This prospective study was done to have a guideline based on the outcome of endoscopy in patients with dyspepsia namely ulcer (ULD), reflux (RLD), dysmotility (DD) either alone or in combination (CTD), with or without alarm symptoms and alarm symptoms alone. Patients attending outpatient department of Medical Gastroenterology with dyspepsia were subjected for UGI endoscopy, after a thorough clinical examination and recording of clinical details in a structured proforma.

EPIDEMIOLOGY

Dyspepsia is extremely common among adults; the prevalence rates reported depend upon the population studied (medical patients versus general population), the survey method used (questionnaire versus interview), the length of the observation period, and the broadness or narrowness of the definition. When symptoms of gastro esophageal reflux (heartburn, regurgitation) are included, prevalence rates are higher than if symptoms are restricted to epigastric pain or discomfort.

Longitudinal studies suggest that dyspeptic symptoms tend to persist or recur frequently in most people. Among patients without prior dyspepsia, the incidence of new onset symptoms is as high as 10%/year; however, in one third of patients these symptoms resolve, thus maintaining an overall prevalence. Dyspepsia is modestly higher in women than in men and surprisingly is seen to decline slightly with age.^{4,5}

Thus, a significant proportion of the population perhaps even the majority – experience dyspepsia, but only one half seek medical attention for these symptoms, most within 6 months of their onset.⁶ Although the reason for consultation is not always clear, the severity or frequency of symptoms, fear of underlying disease (especially cancer), illness in a family member or friend, lower social class, advancing age, anxiety, psychological stress, and lack of adequate psychosocial support are all important factors affecting this decision and needs to be addressed.^{7,8} One fourth of patients consult non-medical practitioners such as nutritionists, acupuncturists, and homeopaths.⁶

PEPTIC ULCER DISEASE

Most peptic ulcers are associated with dyspepsia, but most dyspepsia patients do not have peptic ulcer disease. Nevertheless, it is the first disease considered by most clinicians. The prevalence of peptic ulcers among dyspeptic patients depends upon the population studied. Among such patients selectively referred to gastroenterologists for endoscopy by their primary care physicians, the endoscopic prevalence of ulcers is approximately 12% to 25%.

In studies of unselected dyspeptic patients who consult their primary care practitioners, the prevalence of endoscopic ulcers is approximately 13%. Finally, among subjects in the community at large invited to undergo endoscopy, the prevalence of peptic ulcers is only 8% among dyspeptics and 4% among asymptomatic adults.^{9,10} Thus, the prevalence of peptic ulcers is higher among patients referred by primary practitioners for endoscopy than among unselected patients with dyspepsia.

Peptic ulcers are more common in patients who have the following characteristics: age above 40 years, *Helicobacter pylori* infection (*H. pylori*), NSAID use, night pain, relief of pain with food or antacids, prior history or family history of peptic ulcer disease, male gender, or smoking.⁹

GASTRIC OR ESOPHAGEAL MALIGNANCY

Gastric and esophageal tumors are leading causes of cancer mortality. Gastric or esophageal malignancy is present in fewer than 2% of dyspepsia patients referred for endoscopy. More than 98% of these malignancies are in patients older than 45 years. The lifetime risk of development of esophageal cancer or gastric cancer before the age of 45 is less than 0.1%.¹¹

The risk of gastric malignancy is higher among patients with a previous history of gastric surgery or a family history of gastric malignancy, in immigrants from endemic areas for gastric malignancy, and in patients with *H. pylori* infection.¹²

About 95% of symptomatic adenocarcinoma is advanced, with a 5-year survival rate of 10%. Most advanced lesions are associated with at least one of the warning symptoms: persistent vomiting, GI bleeding, iron deficiency anemia, unexplained weight loss, dysphagia, or an abdominal mass. Although some early and potentially curable malignancies can exhibit symptoms indistinguishable from those of benign disease only 1 in 10,000 dyspeptics have a potentially curable malignancy.

More than 40% of patients who consult physicians report concern about underlying malignancy. Although there is no evidence that endoscopy in dyspeptic patients to detect curable gastric cancer is cost-effective – especially in patients younger than 45 years or without warning symptoms, normal endoscopy findings provide reassurance for both the patient and the physician.¹³

Clinical diagnosis is notoriously unreliable in diagnosing the underlying cause of dyspepsia¹⁴ but a number of alarm features have been suggested as indicating patients at higher risk for serious disease.¹⁵ There is some evidence to suggest that delay in cancer diagnosis occur as a result of failure to investigate patients with alarm features.

FUNCTIONAL (NON ULCER) DYSPEPSIA

Of patients with chronic dyspepsia 50% to 70% do not have a significant focal or structural lesion identified at UGI endoscopy.^{1,9,10} Although further investigation in some cases may reveal other organic causes, over half of chronic dyspepsia patients (less than 12 weeks) have no evident biochemical or organic cause or the symptoms. These patients are labeled as having functional dyspepsia and are an extremely difficult group to manage.¹⁶ Functional dyspepsia is therefore a diagnosis of exclusion. A variety of terms

have been used synonymously, including non-ulcer dyspepsia, non-organic dyspepsia, idiopathic dyspepsia, and essential dyspepsia; the term functional dyspepsia is preferred.

Although symptoms remain chronic in most patients, improvement is noted in up to one half and symptom resolution in one fourth over time.^{10, 17} Limited studies suggest that these chronic symptoms have a significant impact upon quality of life, interfering with daily activities, work, sleep, socializing, eating, drinking, contributing to emotional stress.^{18, 19-21}

APPROACH TO UNINVESTIGATED DYSPEPSIA

In evaluating patients with dyspepsia who have not previously undergone diagnostic investigation (uninvestigated dyspepsia), the physician needs to decide whether UGI endoscopy is necessary to distinguish organic cause of symptoms from functional dyspepsia, or whether a course of empirical treatment could be initiated.

Many patients exhibit mild symptoms of short duration that may resolve spontaneously. The clinical history is of limited utility in distinguishing organic GI disorders from functional dyspepsia. Even experienced clinicians are correct only half the time in distinguishing peptic

ulcer disease from functional dyspepsia on the basis of clinical history alone.²²

Numerous groups have suggested that classification of dyspepsia into subgroups: ulcer-like (ULD), dysmotility-like (DD), reflux-like (RLD) might improve diagnostic accuracy, predict underlying pathophysiologic conditions, and guide empirical treatment.²³ For example, ulcer-like dyspepsia (well-localized pain occurring at night or between meals and relieved by food) might predict a higher likelihood of peptic ulcer disease, whereas dysmotility-like dyspepsia (poorly localized discomfort aggravated by meals and accompanied by postprandial fullness, nausea, bloating or vomiting) might be associated with gastroparesis. With the exception of reflux-like dyspepsia, these sub groupings have proved to have no clinical utility.²⁴ They do not reliably predict the presence or nature of findings on UGI endoscopy nor distinguish between organic causes and functional causes of dyspepsia with sufficient accuracy.²³ Nevertheless, they remain well entrenched among clinicians.

UGI endoscopy allows direct visualization of peptic ulcer, esophagitis, and malignancy with high diagnostic accuracy. However, in many patients, findings at endoscopy, despite establishing a definitive diagnosis, may not alter the initial course of treatment.²⁵

Most patients, irrespective of endoscopic findings, are given a trial of

therapy with an antisecretory agent, usually a proton pump inhibitor. Thus, patients found at endoscopy to have an erosive GERD or a peptic ulcer disease are given a course of a proton pump inhibitor, and those with a H. pylori positive infection are treated with an attempt to eradicate it.

Patients with a normal endoscopic result may have either functional dyspepsia or non-erosive GERD. Despite limited therapeutic benefit, most of such patients are given a trial of antisecretory therapy with either an H₂-receptor antagonist or a proton pump inhibitor. Thus, in patients with dyspepsia without alarm symptoms (i.e., persistent vomiting, GI bleeding, iron deficiency anemia, unexplained weight loss, dysphagia, or an abdominal mass) the advantage of UGI endoscopic evaluation compared with an empirical trial of proton pump inhibitor therapy is unproved.²²

It is suggested that a normal endoscopy may help to allay patient anxieties; however, this reassurance may be of value to only a small number of anxious patients.²⁶

The aim of the clinician therefore is to distinguish those patients who have a high likelihood of having a serious organic disorder warranting further diagnostic evaluation and a definitive diagnosis from the remainder of patients

who may be treated initially with empirical antisecretory therapy and / or H. pylori eradication therapy. Noninvasive testing for H. pylori also can be performed and empirical anti-H. pylori treatment can be given.

With empirical therapy, costly diagnostic studies may be precluded for patients with mild, self-limited symptoms. Patients with continuous or recurrent symptoms can undergo subsequent endoscopic evaluation. Although empirical therapy in a patient with undiagnosed malignancy is undesirable, malignancies are rare in dyspeptic patients without alarm symptoms, and there is no evidence that a delay in diagnosis of several weeks for a course of empirical therapy compromises outcome.

In deciding between empirical management and early endoscopy, the provider therefore must weigh several factors, including the level of patient anxiety, the patient's age, the presence of warning symptoms of disease that increase the likelihood of serious organic disease, the presence of reflux-like symptoms, and infection with H. pylori.¹¹ Such variables make a diagnostic algorithm problematic.

CONSIDERATION OF PATIENT AGE AND/OR ALARM SYMPTOMS

The diagnosis of gastroesophageal malignancy is one of the principal justifications for early endoscopy for dyspeptic patients. Gastroesophageal malignancy however, is extremely rare in patients younger than 45 – 50 years. Furthermore, the incidence of gastric cancer is decreasing in the industrialized world.

In young patients with uncomplicated dyspepsia, the incidence of gastric malignancy is one per million – and the condition is usually incurable.²⁷ Although the likelihood of malignancy increases in patients with dyspepsia who are older than 45 years, the incidence of gastric malignancy is still less than 3%, and most of the individuals affected have at least one of warning symptoms such as dysphagia, severe pain, protracted vomiting, weight loss, fecal occult blood, or anemia.^{9, 10, 22, 28} Therefore, numerous consensus panels have recommended that endoscopy be performed in patients with dyspepsia who are older than 45 – 50 years or have at least one alarm symptom.^{10, 11, 12}

Unfortunately, most cancers exhibiting alarm symptoms are advanced and incurable, and there is no evidence that early endoscopy in patients above

age 45 – 50 who have uncomplicated dyspepsia leads to increased detection of early gastric cancers or improves survival rate.^{11, 22} Despite these facts, current medical and legal standards of care dictate that endoscopy be performed for the evaluation of dyspepsia in older patients and patients of any age with alarm symptoms.

EVALUATION FOR GASTROESOPHAGEAL REFLUX SYMPTOMS

When heartburn or acid regurgitation is a dominant dyspeptic symptom, a presumptive diagnosis of GERD should be made because half to two thirds of patients with reflux like dyspepsia respond to antisecretory therapy.¹¹ Those who do not respond to empirical treatment with a proton pump inhibitor likely do not have GERD and should be evaluated for other causes for dyspepsia.^{24, 29}

TREATMENT OF FUNCTIONAL DYSPEPSIA

Most functional dyspepsia patients have intermittent, mild symptoms that respond to reassurance and life-style modifications. Refractory symptoms, however, may be difficult to manage. Lack of improvement may lead to concern that an organic cause has been overlooked and to repeated testing. Placebo treatment leads to improvement both in dyspeptic symptoms

and in global health status in up to 80% as well as improvement in gastric motility. This finding strongly suggests that a positive physician-patient relationship is essential and therapeutic, potentially obviating myriad tests and pharmacologic interventions.³⁰ The management of functional disorders is summarized as follows:²³

- To determine reasons for consultation at this time so that specific fears or concerns can be addressed. Careful inquiry into the patient's medical, social, and family history may uncover stresses that have led to acute symptom worsening or the current concern with chronic symptoms.
- The recent changes in diet or medications, as causes for symptoms should be ruled out.
- The history and physical examination should be done in a careful, nonjudgmental manner; this action reassures the patient and promotes trust in the physician's judgment and therapeutic plan.
- The diagnostic evaluation that addresses the patient's concerns should be proposed. Over testing, which reflects diagnostic ambivalence and erodes the patient's confidence, unless warranted by changes in symptom pattern or objective findings should be avoided.

- A positive diagnosis of functional dyspepsia, stressing that it is a real disease and providing reassurance about the natural history should be established. The Pathophysiologic processes, including abnormalities of gut motility, heightened visceral sensation, and the importance of the “mind-gut” interaction should be discussed.
- Dietary, emotional, and environmental factors that may trigger symptoms have to be identified. A symptom and food diary may be revealing and encourages the patient to take an active role in disease management. Coffee, caffeine, and excessive alcohol should be avoided.
- Realistic treatment goals should be set because most symptoms are chronic or recurrent, the patient must adapt through lifestyle modifications and coping strategies.
- Drugs to be used judiciously as adjuncts for therapy, not as panaceas. Many patients do not need or want drug therapy once explanations and reassurance have been given.
- Suitable follow-up examination to confirm symptom response should be provided.

- Psychological factors should be explored. Needs referral of patients with psychological or psychiatric problems, a history of physical or sexual abuse, or refractory symptom to a psychologist or chronic pain management clinic.

REVIEW OF LITERATURE

Lord Moynihan's optimistic prediction is that in most patients with dyspepsia, a diagnosis could be made from the history alone has not withstood the test time.³¹ The diagnostic accuracy may be increased to 70% – 80% using a predefined, structured questionnaire but such an approach is unlikely to be adopted by many in busy clinical practice.³²

The need for endoscopy: Predicting clinical requirements for endoscopy depends not only on the knowledge of incidence, prevalence and natural history of GI disease in the community but also on behavior patterns. Some people consult their doctors readily and others may not. The doctors vary widely in their clinical practice. The annual consultations rate in general practice for new episodes of dyspepsia was found to vary from 0.7 – 2.7% in the population. An endoscopic survey of all such patients in one practice showed that about 1/3 have PUD and 1/3 have some other lesion, only 1-2% have carcinoma.³³

The first point to make in such an evaluation is that while an accurate diagnosis of the cause of dyspepsia may be academically desirable but it is not essential for managing most patients. Many will respond to a short course of treatment with antiulcer therapy. Those suspected of having serious disease

based on the presence of alarm symptoms may still be referred for early endoscopy. Those patients who respond to therapy may be reassured. Concern arises if such a delay would harm the patients with peptic ulcer or UGI cancer.

Controlled trials of treatment with placebo or antacid have shown that patients in both groups rarely develop serious complication over 4 – 6 weeks observation.³⁴ There is no definite evidence that this observation over a period of 4 – 6 weeks delay the diagnosis and adversely affects the natural course or surgical cure rate for esophageal or gastric carcinoma.³⁵

Over use of UGI endoscopy and the need for appropriateness

The rapid development of costly medical technology and services would reduce our ability to give all patients the care that would benefit them. Health care system in developed and developing countries are facing a cost crisis. The ability to determine appropriateness of care may be essential to maintain or enhance the quality of care in an increasingly cost conscious environment.³⁶ Health care system should function in such a way that appropriate care be maintained to the needy thereby reducing the unnecessary burden on the medical staff and reducing the unnecessary cost.^{37, 38, 39}

Patients with symptoms suggestive of cancer namely such as dysphagia, anorexia, weight loss, anemia, mass abdomen should require a very early endoscopy. Those patients with ulcer who have evidence of recent substantial hemorrhage should be referred early. Finally, patients who are on non-steroidal anti-inflammatory drugs should be considered for early endoscopy. These patients are often elderly and if they develop complication have increased overall surgical mortality.⁴⁰

A procedure is considered appropriate if its health benefit exceeds its health risk by a sufficient margin that the worth performing.⁴¹ In upto 60% of patients with dyspepsia, the diagnostic evaluation discloses no underlying cause.⁴²

Consensus statements from Europe and United States recommend diagnostic endoscopy for patients with dyspepsia who are older than 45 years of age or patients of any age with unexplained weight loss, vomiting, dysphagia, gastrointestinal bleeding, and anemia ('alarm symptoms'). For patients who are younger than 45 years, decision analysis suggests that the least expensive approach is to forgo endoscopy and to perform serologic tests for H. pylori and to prescribe eradication therapy for those with positive results.

Froehlich et al. from Switzerland in a prospective study regarding the overuse of UGI endoscopy in a country with open access endoscopy have concluded 40% of the endoscopies were rated appropriate, 11% equivocal and 49% inappropriate. The decision to perform UGI endoscopy in previously untreated dyspeptic patients was the most common clinical situation resulting in overuse (5.1%).⁴¹

A consensus statement from American society of Gastro intestinal endoscopy has suggested that GI endoscopy is generally indicated⁴³

- If a change in management is probable based on results of endoscopy.
- After an empiric trial of therapy for a suspected benign digestive disorder has been unsuccessful.
- As the initial method of evaluation as an alternative to radiographic studies.
- When a primary therapeutic procedure is contemplated.

Bersani et al. in Italy have compared two systems (ASGE & EPAGE). In that study they have shown that easy applicability of these systems in their digestive endoscopy service, allowing the continuous monitoring of the endoscopic activities in order to ensure quality and control of the process and outcome indicators. They have shown that by adopting ASGE criteria 89% of cases were appropriate and 11% inappropriate.⁴⁴ By European criteria

adoption 70.3% were appropriate 19.5% were not appropriate and 10.2% were uncertain. The development and application of appropriateness criteria is therefore a complex process, which may vary from place to place.

Rob P. Adang et al. from Netherlands have done a study on appropriateness of indications for diagnostic upper gastrointestinal endoscopy: association with relevant endoscopic disease by prospective study. The proportion of relevant disease for various indications was as signs of UGI bleeding (42.2%); history of peptic ulcer (40.5%); dysphagia (34.4%); anorexia and weight loss (34.3%); isolated dyspepsia with long-term (31.9%), short-term (24.4%), and without therapy (20.9%). Relevant endoscopic findings were observed in 21.0% of dyspeptic patients aged 45 years or less, and in 25.3% of those older than 45 years of age.⁴⁵ The study concludes that the generally approved alarm symptoms should be a reason to perform endoscopy without hesitation. Dyspeptic symptoms, despite adequate empiric treatment, as well as first dyspeptic symptoms in patients older than 45 years should also be a reason for endoscopic investigations. Dyspepsia was present in 54%.⁴⁵ Appropriate use of procedure is an important element of high-quality care.⁴⁶

Kapoor et al. from U.K. in their prospective study have said that fast tract endoscopy in subjects fulfilling current criteria results in a significant yield of cancer (~4%).⁴⁷

Brook et al. has said that all health care systems in developed countries are facing a cost crisis. The explosion of costly medical technologies and medical services increasingly reduces the ability to give all patients the care that would benefit them. A procedure is considered appropriate if its health benefit exceeds its health risk by a sufficiently wide margin so that the procedure is worth performing.³⁶ Dyspepsia is extremely common condition with the prevalence of 22% of the population.

Circumstances appropriate for endoscopy⁴⁸

From the published data, standard practice, and the results of the questionnaire, the audit panel, and American database analysis the working party identified specific indications or symptoms that usually indicate the need for endoscopy - Symptoms or indications for which endoscopy is usually appropriate - gastrointestinal bleeding, unexplained iron deficiency anemia, positive occult blood test result, dysphagia, odynophagia, severe upper abdominal pain, moderate long standing upper abdominal pain, recurrent vomiting, unexplained weight loss, severe heart burn, "Suspicious" barium

meal result, gastric ulcer, check gastric ulcer for healing, achalasia, suspected celiac disease. These indications account for a relatively small proportion of patients referred for endoscopy. Most present with non-specific upper abdominal symptoms, and it is subdivision of this group that is most likely to identify those who are inappropriately referred for endoscopy. Those circumstances in which endoscopy would be appropriate for patients with dyspepsia are - Any patient over the age of 45 with recent onset of dyspeptic symptoms or change in dyspeptic symptoms, patients under the age 45 with dyspepsia who are positive for *Helicobacter pylori* on non-invasive testing or who have other risk factors such as treatment with non-steroidal anti-inflammatory drugs, patients in whom continuous long term treatment with H2 receptor antagonists, acid pump inhibitors, or prokinetic drugs is planned, patients under the age of 45 with severe and persistent symptoms that do not respond to treatment.

Inappropriate - patients of any age who have typical symptoms of irritable bowel syndrome rather than dyspepsia, patients with mild or moderate reflux symptoms which respond to simple measures such as change in lifestyle, antacids, and alginates, patients known to have duodenal ulcer who are responding to treatment, patients who have had a single episode of dyspepsia and are now asymptomatic and not receiving treatment.

Patients over the age of 45 with a recent onset of dyspeptic symptoms or change in dyspeptic symptoms -These patients should have endoscopy at an early stage so as not to miss gastric cancer.⁴⁹ This disease is the fourth commonest lethal malignancy in England and Wales, accounting for over 10000 deaths a year. Surgery has most benefit in patients with early gastric cancer--that is, where the lesion is confined to the mucosa and submucosa but not invading the muscularis propria.^{50, 51} Such patients present with mild symptoms that are often indistinguishable from benign disease.⁵² In the United Kingdom cancer is rare under the age of 45. The American system would prefer all patients with dyspepsia to receive a trial of treatment first. British Society audit panel rejected this argument.

Florian Froehlich et al. study had shown 46% of UGI endoscopy was judged to be appropriate and 39% inappropriate and 15% uncertain by the explicit criteria.⁵³

AIM OF THE STUDY

- To determine the outcome of endoscopy among dyspeptics with and without alarm symptoms.
- To determine the outcome of alarm symptoms on endoscopy.
- To identify the cut off age for an early endoscopy amongst dyspepsia with no alarm symptoms.
- Appropriateness of indications for diagnostic UGI endoscopy in association with relevant endoscopic disease.

MATERIALS AND METHODS

All individuals, belonging to either sex and irrespective of the age, with a clinical diagnosis of dyspepsia – ulcer / reflex / dysmotility either alone or in combination, with or without alarm symptoms and alarm symptoms alone registered between January 2004 and June 2005 were included in the study. The patients were attending the Department of Medical Gastroenterology of Stanley Medical College Hospital, Chennai. Patient details which included demographic data and social habits: smoking, alcoholism and use of NSAIDs were documented in a pre-structured proforma (Annexure I). Clinical details included the type of dyspepsia, duration of symptoms, presence or absence of alarm symptoms either alone or in combination: anorexia, weight loss, dysphagia, GI bleed, mass epigastrium and anemia. Endoscopy was performed within a week of registration so as to avoid a long wait period and to determine the appropriateness of an early endoscopy. Patients with a GI bleed had an endoscopy within 24 hrs of the bleed. The outcome of endoscopy was noted and categorized as **normal**, **benign and malignant**. Benign findings included: esophagitis, esophageal webs, gastritis, erosive and ulcer lesions of the stomach and duodenum. A lesion was considered as malignant if it had the characteristics of malignancy at endoscopy. Biopsy was not considered necessary, since even a negative biopsy would warrant a second or third look in a suspicious malignant lesion.

The outcome of the endoscopy was correlated with the duration of illness, age of the patient, clinical presentation and the clinical history. The cut off age for an early detection of carcinoma of the stomach in dyspepsia was derived. Also the outcome of the various alarm symptoms was studied for the three types of lesions.

All the patients undergoing endoscopy were categorized as

I. Gp I: Individuals with dyspepsia

Subtypes:

i. Ulcer like

ii. Reflux like

iii. Dysmotility like

iv. Combination type

Gp II: Individuals with dyspepsia and Alarm

(dysphagia/anorexia/weight loss/GI bleed/
anemia/mass epigastrium: either alone or in
combination)

Gp III: Individuals with isolated alarm symptoms

(dysphagia/anorexia, weight loss/GI bleed/
anemia/mass epigastrium: either alone or in
combination)

Hospital ethics committee approval was obtained, written and informed consent by the patient were obtained before undertaking the study.

EXCLUSION CRITERIA

Individuals with a known diagnosis and who were on follow up or were diagnosed as a case of carcinoma stomach, post operative cases, individuals with chronic liver disease, those undergoing endoscopy for therapeutic indications or for exclusion of ulcer disease pre-operatively in those with epigastric hernia / incisional hernia or for a duodenal biopsy in malabsorption state and corrosive injury were excluded from the analysis.

STATISTICAL ANALYSIS

Demographic and social habits were expressed as frequencies in percentage and analysed by using Pearson's Chi – square test. Cut off age for malignancy was computed using ROC curve. Diagnostic tests like sensitivity and specificity was calculated to obtain an optimal cut-off age. Correlation between age and malignancy was obtained using scatter diagram.

RESULTS

A total 3432 endoscopies were performed during the study period. There were 2068 men and 1364 women (M: F ratio: 1.5:1). The overall mean age was 41.6 ± 15 years (range: 7-85 years).

Mentioned below are the numbers of patients in the 3 major groups and the subtypes of Gp I

Gp I (Dyspepsia):	2,763 patients (80.5%)
a. Ulcer-like:	1,898 (68.6%)
b. Reflux – like:	319 (11.5%)
c. Dysmotility like:	193 (7%)
d. Combination type:	353 (13%)
Gp II (Alarm + Dyspepsia):	222 (6.5%)
Gp III (Alarm alone):	447 (13%)
Dysphagia:	231 (51.7 %)
Anemia:	26 (5.8%)
Mass epigastrium:	4 (<1%)
GI bleed:	68 (15.2%)
Combination (Anorexia, weight loss & others)	118 (26.4%)

Table 1. Demographic characteristics in the 3 groups of patients.

	Gp I (2673)				Gp II (222)	Gp III (447)
	ULD	RLD	DD	CTD	A + D	Alarm alone
Total pts.	1898 (68.7)	319 (11.5)	193 (7)	353 (12.8)	222 (6.5)	447 (13)
Mean age	41	38.3	41.8	39.7	45.3	46.2

A + D: Dyspepsia with Alarm

Table I. summarizes the age, sex distribution and other demographic characteristics in the 3 groups of patients. 80% of patients had dyspepsia. In all the groups men predominated. The mean age was between 38 years to 46 years. Smoking, alcohol and use of NSAIDs intake were more common in patients with ulcer-like dyspepsia.

>64	204	9.9%	111	8.1%

Table 4 shows the number of patients under each age group in either sex. As there was no difference in proportion in age distribution in either sex, the results were analyzed together.

Table 5. Duration of Symptoms and Outcome of endoscopy

Duration (Months)	Normal	Benign	Malignant	Total
	No. (%)	No. (%)	No. (%)	
<1	153 (38.8)	204 (51.8)	37 (9.4)	394
1-3	207 (33.3)	299 (48.1)	116 (18.6)	622
3-6	386 (34.0)	637 (56.1)	113 (9.9)	1136
6-9	184 (37.0)	304 (61.2)	9 (1.8)	497
9-12	212 (63.7)	116 (34.8)	5 (1.5)	333
>12	311 (69.1)	135 (30.0)	4 (0.9)	450
Total	1453	1695	284	3432

Table 5 shows the correlation between the duration of illness and the outcome of endoscopy. There was an inverse relation between the duration of illness and malignant outcome at endoscopy. This was statistically significant ($\chi^2= 372.2$ $p=0.001$). Malignant lesions were common when duration of illness was < 6 months, those between 6 and 9 months had benign disease or a normal endoscopy and those symptomatic for more than 9 months had a normal endoscopy.

The endoscopic prevalence of common benign lesions observed in our study was duodenal ulcer (10.9%), gastric ulcer (5.3%), esophageal ulcer (<1%), esophagitis (5.1%), erosive gastritis (12.2%), duodenitis (7.7%). Achalasia cardia, CP web, Barrett's esophagus and benign stricture of the esophagus were noted in <1%. (Fig.2). 569 patients had peptic ulcer (DU 373, GU 196). Males had ulcer disease 1.55 times higher than females. The overall prevalence of peptic ulcer disease was 16.6%.

Fig 2. Relevant benign endoscopic findings in our study

Table 6. Outcome of endoscopy in 3 groups

		Outcome			Total
		Normal	Benign	Malignant	
Gp I	UTD	776 (40.9)	1015 (53.5)	107 (5.6)	1898
	RTD	173 (54.2)	143 (44.8)	3 (0.9)	319
	DD	93 (48.2)	97 (50.2)	3 (1.6)	193

Gp III		153 (34.2)	183 (40.9)	111 (24.8)	447
Total		1453	1695	284	3432
Mean age		38.71 ± 14.68	41.93 ± 14.46	54.58 ± 12.88	

Table 6 shows the outcome of endoscopy in the III groups. Malignant lesions were statistically significant in patients with alarm (p=0.001). Overall, there were 42.3 % who had a normal endoscopy and 49.3% had benign lesions. There were significantly more cases with a normal or a benign lesion in all the groups of patients more so in Gp I compared to Gp II and III indicating an over cautiousness on clinical symptomatology. Only one-quarter of patients in Gp II and Gp III had a malignant lesion.

Fig 3. Shows the outcome of endoscopy in 3 Groups in either sex

N – Normal, **B** – Benign, **M** – Malignant

Table 7. Outcome of endoscopy in different age groups

Age group in Years	Outcome with %			Total
	Normal	Benign	Malignant	
<25	243 (56.4)	185 (42.9)	3 (<1%)	431
25-34	371 (48.9)	367 (48.4)	21 (2.8)	759
35-44	361 (45.7)	401 (50.8)	28 (3.5)	790
45-54	226 (33.8)	368 (55.1)	74 (11.1)	668
55-64	161 (34.3)	219 (46.7)	89 (19.0)	469
>64	91 (28.9)	155 (49.2)	69 (21.9)	315
Total	1453	1695	284	3432

6% of malignant lesions were noted between 25 and 45 years of age with 3.5% between 35 – 44 years.

Fig 4. Shows malignancy in different age categories in 3 Groups in either sex.

The onset of malignant lesion was by the age of 35. Subsequent increase was noted with advancing age.

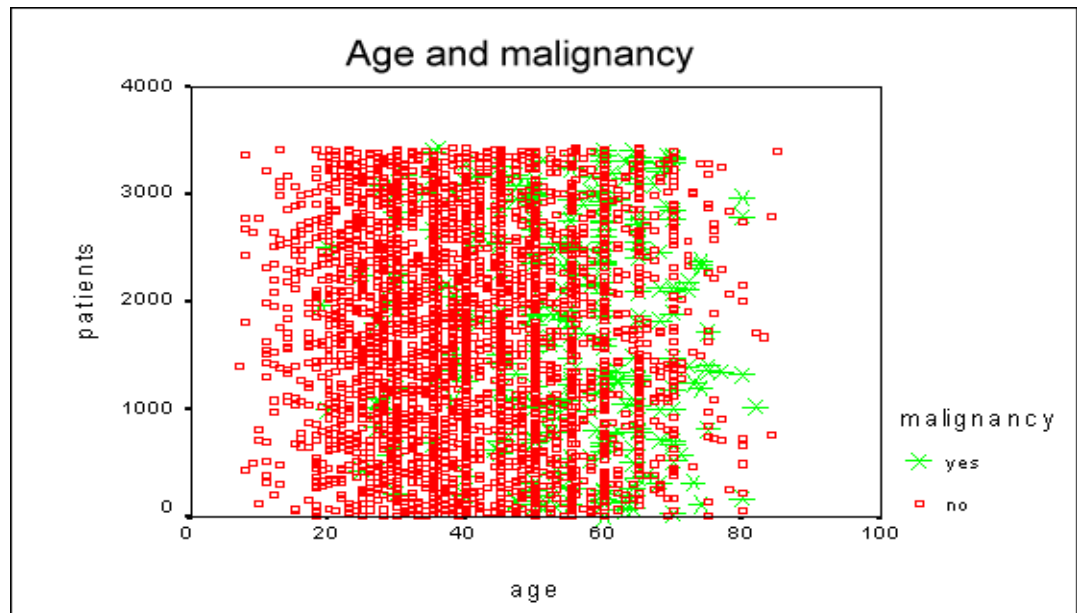

Fig 5. The scatter diagram shows the distribution of malignancy with age groups.

Coordinates of the Curve for cut off age group

Table 8. Cut off age group for malignancy

Positive if Greater Than or Equal To (a)	Sensitivity	Specificity
.00	1.000	.000
<25	.989	.136
25-34	.915	.370
35-44	.817	.612
45-54	.556	.811
55-64	.243	.922
>64	.000	1.000

The cut off age was 35 – 44 obtained by sensitivity and specificity tests.

Table 9. Test Result Variable(s): age group

Sex	Positive if Greater Than or Equal To (a)	Sensitivity	Specificity
Male	.00	1.000	0.000
	1.50	.985	.144

	2.50	.946	.374
	3.50	.866	.624
	4.50	.569	.808
	5.50	.228	.915
	7.00	.000	1.000
Female	.00	1.000	000
	1.50	1.000	.139
	2.50	.841	.375
	3.50	.695	.610
	4.50	.524	.805
	5.50	.280	.931
	7.00	.000	1.000

Using the co-ordinates of curve sensitivity and specificity (Table 8 and 9 & figs 6, 7), the cut off age for malignancy was between 35 and 44 years. For the female, the optimum cut off age was 38 yrs and for males 43.5 years.

Fig 6. The cut off age for malignancy was computed using ROC curve (Male 43.5 yrs)

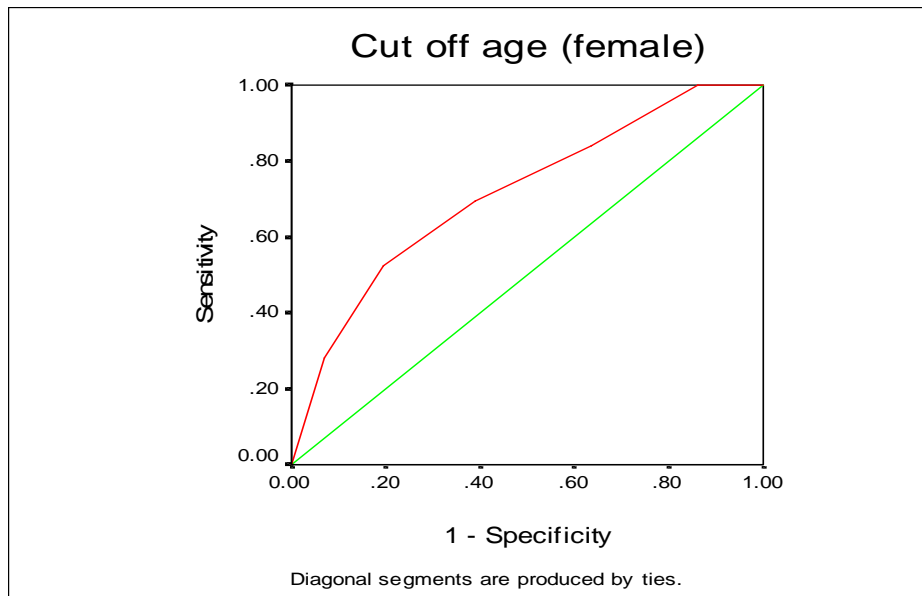

Fig 7. The cut off age for malignancy was computed using ROC curve (Female 38 yrs)

Table 10. Shows the outcome of endoscopy in individuals with various types of alarm in **Gp II** and **III**

Alarm	Outcome (%)			Total
	Normal	Benign	Malignant	
Dysphagia	68 (27.5)	86 (34.8)	93 (37.7)	247
Anemia	13 (39.4)	17 (51.5)	3 (9.1)	33
Bleeding	39 (39.4)	52 (52.5)	8 (8.1)	99
Mass Abd	1 (25.0)	1 (25.0)	2 (50.0)	4
Vomiting	36 (30.0)	58 (48.3)	26 (21.7)	120
Combination	73 (44)	66 (39.7)	27 (16.3)	166
Total	230	280	159	669

$\chi^2= 54.4$ P=0.001

Univariate analysis was done to find the outcome of alarm symptoms. Only one-third of patients with dysphagia had a malignant lesion indicating an over cautious approach towards this symptoms. Using the univariate analysis dysphagia alone was associated with esophageal malignancy. 56% of malignant patients had alarm symptoms either alone or in combination. A quarter of patients with alarm symptoms had a malignant pathology. 5 patients had duodenal malignancy in group I.

Table 11. Summarizes the outcome of a malignant pathology at endoscopy in the 3 groups of patients

	Ca esophagus		Ca stomach		Total
	M	F	M	F	
Gp I	8 (6.6)	4 (3.3)	77 (64.1)	31 (26)	120
Gp II	1 (2.0)	2 (4.0)	36 (75)	9 (19)	48
Gp III	61 (54.9)	27 (24.3)	18 (16.2)	5 (4.5)	111

In group I, significant proportion of individuals had carcinoma of the stomach, more so amongst men. Carcinoma oesophagus was common in those with alarm symptoms (Gp III) i.e. 80%.

DISCUSSION

Dyspeptic symptoms, which have a high prevalence and incidence in the population, are the most frequent reason for requesting an UGI endoscopy. It is not uncommon for many young patients with simple dyspepsia being investigated. The uncertainty regarding which patients with dyspepsia should undergo UGI endoscopy is not clear. 87% of patients had dyspepsia in our study. Dyspeptic symptoms overall are common in the general population and it is not clear whether the incidence of malignancy in patients with uncomplicated dyspepsia is different from that of population without dyspepsia.²⁷

Also guidelines for appropriate use of UGI endoscopy may result in a more rationale selection of patient world over. Clinical history and examination shows a diagnostic accuracy of only 45-50%. The accuracy increases to 70-80% on using a predefined questionnaire. The latter is time consuming and is not practical in day-to-day practice. Performing an endoscopy for all patients is also not practical especially with the increase workload in the endoscopy suite. Clinical diagnosis is unreliable in diagnosing underlying cause of dyspepsia.¹⁴ The role of an empirical therapy has been highlighted by earlier workers.⁵⁴

Several studies have examined the discriminant value of various alarm symptoms for identifying the 'high risk' patients for early referral.^{32, 55} Unlike the West, there are no set guidelines for Indian patients to predict an appropriate outcome. The set guidelines are essential in order to enhance the quality of health care, reduce the cost, to avoid unnecessary workload and these needs to be tailored. The present study was undertaken, to prospectively evaluate the outcome of endoscopy in patients with dyspepsia with or without alarm and those with alarm symptoms alone and to propose guidelines for an appropriate outcome amongst dyspeptics in the South Indian population of Tamil Nadu.

A number of alarm features have suggested as indicating patients at higher risk of a serious disease.^{10, 15} These features include the recent onset of dyspepsia in an older subject, occurrence at any age of the so-called alarm symptoms: dysphagia, vomiting or weight loss.

Age is an important criterion while screening patients with dyspepsia for cancer. Amongst the western population, the incidence of esophageal and gastric cancer is very low below the age of 45 and these recommendations do not justify the use of endoscopy in these patients to detect an early cancer.³⁵ As per the ASGE report only 1% of all dyspeptic patients will have an esophageal or gastric cancer, and only 6 per 10,000 patients will have 'early'

gastric cancer at endoscopy.³⁵ These criteria may not hold true in regions with high prevalence of gastric and esophageal cancer. In the present study, 5.6% of individuals with dyspepsia had a malignant lesion, more often a carcinoma of the stomach. There was a male preponderance. The cut-off age for the South Indian population of Tamil Nadu appears to be 35 years.

Recommendations world-over is for the empirical treatment for 4 to 6 weeks with antacids and H2RA for patients with dyspepsia and those below the age of 45. For our population, an empirical treatment can be recommended for those dyspeptics below the age of 35 provided they have no alarm symptoms, and an endoscopy can be performed after 4 to 6 weeks of registration. Studies have shown that serious complications seldom occur during the observation period.³⁴ Also there is no evidence that a four to six week delay in diagnosis would adversely affect the natural course or a surgical cure rate of esophageal or gastric cancer.³⁵

Most studies recorded normal UGI endoscopy in dyspepsia varying from 30-40%.⁵⁶ In the present study, 1453 patients had normal endoscopy (48.7%). The uncertainty about the most appropriate use of UGI endoscopy in the context of cost may result in under use of the procedure. *Florian Froehlich et al.* found an under use of UGI endoscopy in 11.8%. This is the only study which has looked into the under use of UGI endoscopy.⁵⁷

Florian Froehlich et al. reported an overuse of UGI endoscopy in 63 out of 611 patients with dyspepsia. 49% of procedure was considered as inappropriate. Overuse was seen in 5.1%.⁴¹ In the present study the inappropriate use of UGI endoscopy was 42.3%. They concluded that 70% of all potential indications for UGI endoscopy, the risk of missing a pathology was so great that they rated them as appropriate i.e. UGI endoscopy must be offered to these patients.

Symptoms of early gastric cancer are indistinguishable from benign condition, whereas presence of established alarm symptoms may signify the presence of advanced inoperable disease. In a study from Scotland has suggested that only 7% of cancers in those patients over 55 years presented without alarm features.⁵⁸ The yield of cancer in simple dyspepsia is low and that only a small proportion of those cancers identified are resectable.⁵⁹ In the present study 125 patients had cancer in absence of alarm with a prevalence of 3.6% in simple dyspepsia.

Data from the UK⁶⁰ and Europe suggest that approximately 10% of dyspeptic patients have alarm symptoms. *Kapoor et al.* determined the predictive value of alarm symptoms in a cohort of 1852 patients undergoing UGI endoscopy. The mean age was 59 years, and the prevalence of cancer was 3.8% and serious benign pathology in 12.8%. In the present study , alarm

symptoms were noted in 19.5% of the total study population. The mean age for cancer was 54 ± 12 years. Cancer prevalence was 8.2%, gastric ulcer was 5.3%. The predictive value as odds ratio (OR) for dysphagia was 3.1, weight loss 2.6 and 9.5 for age > 55 years in *Kapoor* study. All these were found to have a PPV for risk of cancer. In the present study dysphagia was significantly associated with a malignancy followed by combination of alarm (26.4%). Majority of our patients are from a low socioeconomic status. Hence the higher rate of malignancy in this population is not surprising. *Adang et al.* found that generally recognised alarm symptoms have been associated with demonstrable relevant endoscopy disease. i.e. ulcer disease, gastric or esophageal malignancy. Also older patients were referred for alarm symptoms and less often for dyspepsia than younger patients. Early UGI cancer may be asymptomatic and diagnosed by chance in subjects complaining of dyspeptic symptoms that are secondary to benign or functional cause.

The yield of endoscopy was low in patients referred for isolated dyspepsia particularly when < 45 years of age. A similar observation was made in the present study wherein 975 patients < 45 years of age had normal UGI endoscopy. As per the British Society guidelines, 45 years is taken as cut off for performing UGI endoscopy. In an earlier retrospective audit on UGI endoscopy from Coimbatore, malignant lesions were uncommon below the age of 35. Rising incidence of esophageal and gastric cancer was seen in

the subsequent decades.⁶¹ In our study, malignancy was noted in 3.5% of patients belonging to the age group between 35 and 44 with a peak around 40 years. By sensitivity and specificity tests malignancy was found to be significant in the age group between 35 and 44 years. By ROC curve analysis, females developed malignancy 5 years earlier than the male population in our study. As cancer was noticed at younger age when compared to the west, 35 years may be an ideal cut off age for UGI endoscopy for screening early GI cancer in South Indian population. In Adang's and other studies, prevalence of clinically relevant endoscopic disease was 30%. This was similar to our study, which showed esophagitis 5.1%, Du 10.9%, Gu 5.3% being the most frequent finding. In most of the studies, age was a determinant factor for a high diagnostic yield of UGI endoscopy. Definition of relevant versus irrelevant disease is arbitrary and may differ in various health care systems. Sonnenberg and Townsend have shown that any diagnostic test with a probability of 20% to discover treatable disease to be cost effective. A delay of a few weeks in favour of an empirical therapy seems reasonable in a subset of patients with early UGI cancer. Persistence of symptoms beyond 6 weeks should allow one to perform endoscopy in this subset of patients.

In the present study, alarm symptoms were associated with a significant outcome at endoscopy, though 68 patients with dysphagia had

normal endoscopy, indicating an over cautious approach towards our patients. Despite this, an early endoscopy within a week is desired in patients with any of the alarm symptoms either alone or in combination.

45 years of age has been proposed as a cut-off in regard to the question whether or not to investigate dyspepsia as an isolated symptom. Earlier studies have shown high prevalence of esophageal and gastric cancer in South Indian population. The prevalence of cancer was noted to increase above the age of 35. In the present study, 6% malignant lesions were seen < 35 years with significant increase between 35-44 years.

SUMMARY

- Dyspepsia constituted 80.5% of all cases, dyspepsia with alarm 6.5% and alarm alone 13%.
- Ulcer like dyspepsia was the most common type of dyspepsia, dysphagia was the most common alarm symptom.
- Males were slightly more than females in all the three groups.
- Most of cases with dyspepsia were in the age group between 25 and 45 years.
- Onset of alarm symptom was by 35 years of age.
- Inverse relationship was noted between the duration of the symptom and the outcome of a malignant pathology i.e. lesions were benign or normal when the duration was more than 6 months.
- Malignant lesions were significant in the alarm group.
- Normal endoscopy was present in 42.3% and benign lesions in 49.3% seen in all age groups.
- Malignant lesions manifest by the age of 25 years and increases proportionally in subsequent decades.
- The cut-off age for malignancy was 38 years for females and 43.5 years for males.
- Dysphagia was the single alarm symptom associated with high yield of malignancy at endoscopy.
- Among patients who were detected to have malignancy gastric cancer was seen in 62% and esophageal cancer in 38%.

Summarising

An early endoscopy is recommended in patients with persistent pain, dysphagia, vomiting, anorexia and weight loss as it would favour a cancer and warrants an early endoscopy. Other patients who require an early endoscopy are the elderly and those on long term NSAIDs.

PROPOSAL OF GUIDELINES

British Society of Gastroenterology has proposed guidelines and has suggested a 2-week wait period to undergo UGI endoscopy and evaluate the cause for dyspepsia. The present study attempts to propose guidelines for the south Indian population that will improve the outcome of an endoscopy both in terms of diagnosis and management:

- Dyspepsia with no alarm symptoms, age less than 35, duration of illness more than 6 months can be treated empirically with H2RA or antacid. If symptoms persist at the end of 4 weeks UGI endoscopy is to be done **within one week**
- Dyspepsia + Alarm or any of the alarm symptoms alone: UGI endoscopy **within one week**
- Dyspepsia above the age of 35 years, newly acquired alarm symptoms or persistence of symptoms or recurrence during or after empiric therapy: UGI endoscopy **within one week**
- Patients with symptoms suggestive of cancer: dysphagia, anorexia, loss of weight: UGI endoscopy **within one week**.

CONCLUSION

Indication for endoscopy needs to be tailored according to the clinical presentation in dyspepsia. Individuals below the age of 35, in the absence of alarm symptoms can be managed with an empirical anti peptic therapy and reviewed at the end of 4 weeks. Persistence of symptoms should warrant an early endoscopy. Those with alarm symptoms require an endoscopy within one week. A normal endoscopy in dyspepsia cannot be readily dismissed as irrelevant. Reassurance provided by normal findings may subsequently result in fewer symptoms, avoidance of unnecessary treatment and decreased consultation rate. For the future, the current guidelines laid down in this study needs extrapolation and prospective validation in different regions of the country.

ABBREVIATIONS

A - Anemia
APP - Anorexia
ES - Early satiety
(W) - Weight loss

NS - Normal study
D1 - Duodenitis
G1 - Gastritis
O1 - Esophagitis
D2 - Duodenal ulcer
G2 - Gastric ulcer
O2 - Esophageal ulcer
D4 - Duodenal Malignancy
G4 - Gastric Malignancy
O4 - Esophageal Malignancy
DE - Erosive duodenitis
GE - Erosive gastritis
GOO - Gastric outlet obstruction
CP WEB - Cricopharyngeal web
SRH - Stigmata of Recent Hemorrhage
MW TEAR - Mallory Weis tear
NED - Non Erosive Duodenitis
NEG - Non Erosive Gastritis
