A Dissertation on

STUDY ON ADOLESCENT GYNAECOLOGICAL PROBLEMS

Dissertation submitted to

THE TAMIL NADU Dr.M.G.R.MEDICAL UNIVERSITY

CHENNAI.

in partial fulfilment of the regulations

for the Award of the degree of

M.S., (Obstetrics & Gynaecology)

Branch – II

INSTITUTE OF SOCIAL OBSTETRICS AND GOVT. KASTURBA GANDHI HOSPITAL FOR WOMEN AND CHILDREN

MADRAS MEDICAL COLLEGE

CHENNAI.

APRIL 2015

BONAFIDE CERTIFICATE

Certified that this dissertation is the bonafide work of **Dr. RADHE AKANG** on **"STUDY ON ADOLESCENT GYNAECOLOGICAL PROBLEMS"** during her M.S., (Obstetrics & Gynaecology) course from April 2012 to April 2015 at the Institute of Social Obstetrics, Government Kasturba Gandhi Hospital for Women and Children, Madras Medical College, Chennai.

Prof.Dr.T.G. Revathy, M.D, D.G.O.,
Professor & Chief of the Department
Dept. of Obstetrics & Gynaecology,
ISO-KGH
Madras Medical College
Chennai.

Prof.Dr. Baby Vasumathi, M.D., D.G.O.,
Director
ISO-KGH
Madras Medical College,
Chennai.

Prof. Dr. R. VIMALA, M.D,
DEAN,
Madras Medical College &
Rajiv Gandhi Government General Hospital,
Chennai.

Date :

DECLARATION

I solemnly declare that the dissertation titled **"STUDY ON ADOLESCENT GYNAECOLOGICAL PROBLEMS"** is done by me at **INSTITUTE OF SOCIAL OBSTETRICS AND GOVT. KASTURBA GANDHI HOSPITAL FOR WOMEN AND CHILDREN,** Madras Medical College under the guidance and supervision of **Prof. Dr.T.G.Revathi M.D., D.G.O.,** Professor of Obstetrics and Gynaecology, Madras Medical College, Chennai.

This dissertation is submitted to the Tamil nadu Dr. M.G.R Medical University towards the partial fulfillment of requirements for the award of M.S. Degree (Branch II) in Obstetrics and Gynaecology.

Place : Chennai

Date :

Dr. Radhe Akang

ACKNOWLEDGEMENT

I Thank **Dr. R. Vimala, M.D.,** Dean Madras Medical College for permitting me to conduct this study in Institute of Social Obstetrics and Government Kasturba Gandhi Hospital for Women and Children, Chennai.

I owe my sincere thanks to **Prof. Dr.Baby Vasumathi, M.D. D.G.O.** Director, ISO – KGH for her valuable guidance, during the study.

I express my profound gratitude to my guide **Prof.Dr.T.G. Revathy, M.D., D.G.O.,** Professor of Obstetrics and Gynecology for her unwavering support and encouragement.

I also my sincere thanks to **Prof. Dr. S. Dilshath, M.D, D.G.O., Former Director, ISO – KGH** for her support and encouragement.

My gratitude to my Assistant Professors, Statistician **Mr.Ravanan** my colleagues and Hospital Staff and patients for enabling me to complete the study.

CONTENTS

INTRODUCTION

Puberty coined from latin word 'Pubertus' meaning 'grown up' (**Foster 1992). "**Puberty is the period of physiological changes in secondary sexual characteristics development and their attainment of capability of sexual reproduction". Puberty not only deals with mere physiological changes but there is also tremendous psychological and emotional changes in the life of the adolescent. Adolescence, in simple words is nothing but the phase of life during which a carefree child becomes the responsible adult.

"WHO defines adolescence as the period in human growth and development that occurs after childhood and before adulthood, from age 10-19 years". It is an ongoing process i.e; the psychological and physiological changes which occur may begin before and even can continue after this age(**Progress in Obstetrics and Gynaecology, vol 12; John Studd**).

The biological determinant of adolescence are universal, however there may be variation in the duration, defining charactecristics of this phase across time, demographic area, culture and socioeconomic conditions. Over the passage of time, there have been many changes in

the pattern of this period like the time of onset of puberty, urbanization, changing attitude towards sexuality, behavior etc.

Adolescence in girls has been regonised as a special phase in their life. It requires a specific approach and special attention. This period of transition makes them vulnerable to various problems e.g., general, reproductive health related, sexually related and psychological problems. This period in a girl's life is the preparation for safe motherhood. These adolescent girls are the direct reproducer for the future generation. So, the health of these girls not only influences her own health but, also the health of future generation.

Reproductive health related problems of adolescent girls has its own special space in the spectrum of gynaecological problems of all ages. This is because of its unique presentation and association with emotional and psychological factors.

Today, adolescent forms 20.9% of total Indian population **(Population Census of India 2011)** and their health determines the health of the nation. Adolescent sexual and reproductive health forms a major component of global burden of sexual ill health but has been historically overlooked in terms of sexual and reproductive health intervention . Though, FOGSI has dedicated the year 1999 as the year for

adolescent health and addressed the need for adolescent health clinics but still it remains a sub specialised area of gynaecology which still needs a great deal of attention.

With this preview, my thesis titled ‘ **Study on adolescent gynaecological problems’,** I have made an attempt to review and analyse various gynaecological problems and factors responsible for development and progression of these problems in adolescent girls attending gyanecological OPD and emergency casualty in ISO & KGH Hospital

AIM OF THE STUDY

To study various gynaecological problems encountered in adolescent girls who attended the gynaecological out patient department of Obstetric and Gynaecology in ISO & Kasturba Gandhi hospital for women and children, Triplicane.

To analyse different causes of the gynaecological problems in adolescent girls in age 13-19 years.

REVIEW OF LITERATURE

Puberty is the phase of life in which there is a transition from childhood to adulthood. There is development of secondary sexual characteristics, onset of menstruation and also the sexual reproduction capability. Puberty includes a series of events which are predictable but vary in timings, pace and also in sequence. It initiates through a cascade of endocrinal changes that leads to sexual maturation and reproductive capability **(Patton and Viner 2007)**

TIMING OF PUBERTY :

The age of puberty occurs earlier these days than in the past. It generally starts earlier in girls than in boys. There are various determinants of the timing of the puberty onset like nutritional status, geographical location , general health, exposure to light, psychological state. But the major determinant is no doubt genetics. The average age of menarche has declined in recent years, according to a study published in the journal Paediatrics .This decline in the age of menarche has also been attributed to the improved nutrition and healthier living condition **(Patton and Viner 2007).**

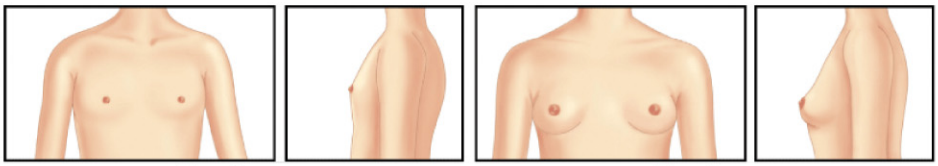
There has been various researches showing influence of ethnic backgrounds, body mass index , family income on the onset of puberty. Menarche occurs earliest in those girls whose BMI falls under the obese category(upto 20% above normal weight for age), followed by normal weight, then underweight and lastly the girls who suffers from anorexia. But, it is to be noted that the pathological obesity is associated with delayed puberty rather than earlier onset. Conditions like chronic illness, strenuous physical activity as in atheletes, malnutrition are responsible for delayed puberty in some. Puberty starts earlier in those staying in low altitude areas than those in high altitude.

PHYSICAL CHANGES OF PUBERTY :

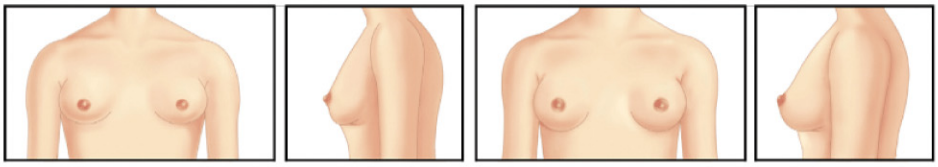
The most frequently staging system to describe the physical changes of puberty was described first by **Marshall and Tanner in the year 1969**. The physical change constitute three main components :

a) Secondary sexual characteristics
b) Gonadal development and function leading to menarche
c) Growth spurt

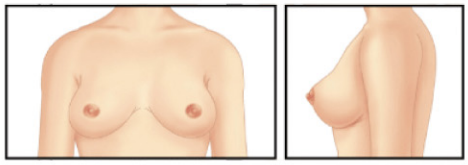
The typical sequence includes thelarche , adrenarche , growth spurt and menarche.



Stage 1 Stage 2



Stage 3 Stage 4



Stage 5

Stage 1 Preadolescent: juvenile breast with elevated papilla and small flat areola.

Stage 2 The breast bud forms under the influence of hormonal stimulation. The papilla and areola elevate as a small mound, and the areolar diameter increases.

Stage 3 Continued enlargement of the breast bud further elevates the papilla. The areola continues to enlarge; no separation of breast contours is noted.

Stage 4 The areola and papilla separate from the contour of the breast to form a secondary mound.

Stage 5 Mature: areolar mound recedes into the general contour of the breast; papilla continues to project.

Source: Kappy MS, Allen DB, Geffner ME: *Pediatric Practice: Endocrinology:* www.accesspediatrics.com

PHASES OF PUBERTAL GROWTH:

Phase 1 (Thelarche) :

The first sign of puberty is the development of breast. It indicates the competency of HPO axis. Marshall and Tanner described the breast changes in five stages :-

Tanner stage 1(B_1) **:** Pre pubertal state, no palpable breast tissue, with areolar less than 2 cm in diameter.

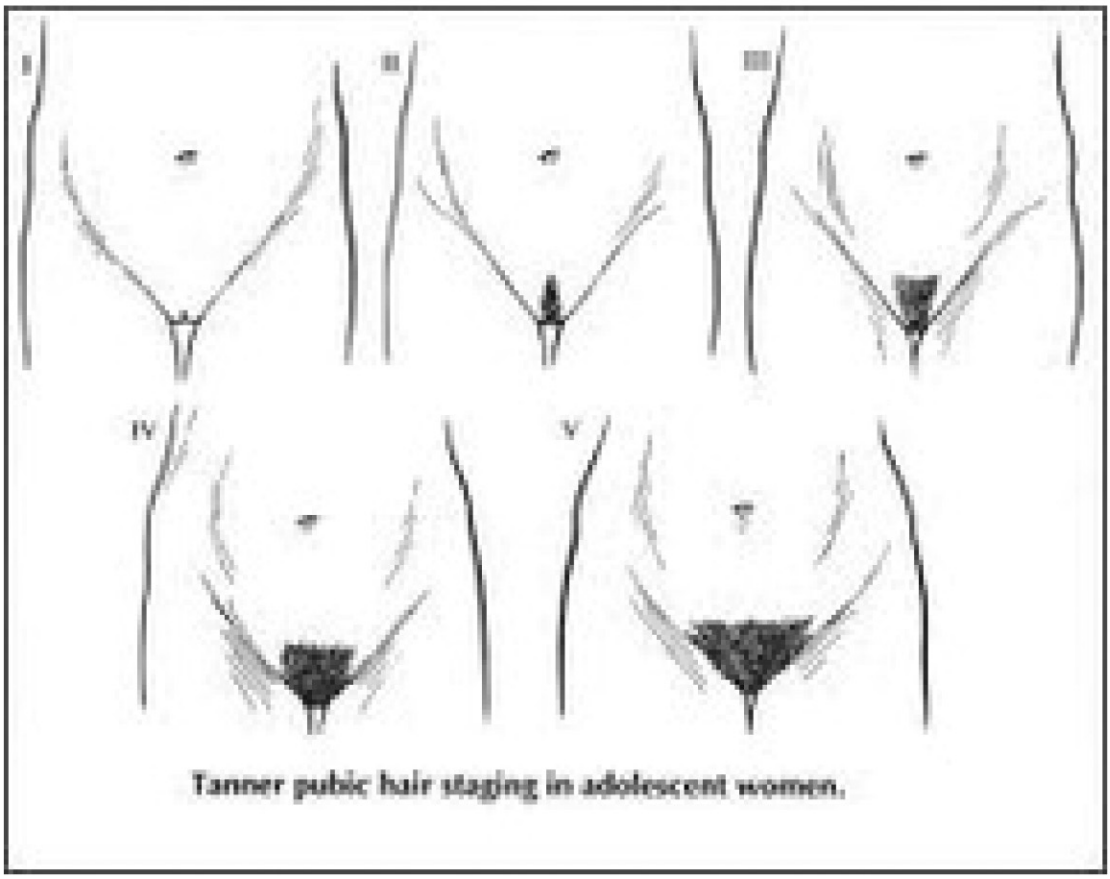
Tanner stage 2(B_2) **:** Breast budding occurs, visible and palpable mould of breast tissue

Tanner stage 3(B_3) **:** Further enlargement and elevation of the entire breast.

Tanner stage 4(B_4) **:** Projection of areola and papillae to form a secondary mould above the level of breast.

Tanner stage 5(B_5) **:** Breast is mature in contour and proportion. Areola receeds into the general contour of the breast.

According to the Copenhagen Puberty study (Paediatrics Vol.123, No. 5, May 2005), there is a decline in the age at breast development.



Tanner pubic hair staging in adolescent women.

Phase 2 (Adrenarche) :

It indicates the rise of adrenal androgen secretion with a rise in blood level of DHEAS and androstenedione. This ultimately results in the growth of pubic and axillary hair(pubarche).

Tanner stage 1 : No sexually stimulated pubi hair

Tanner stage 2 : First appearance of sparse growth of long coarse and crinkly hair along the labia majora.

Tanner stage 3 : Hair are coarser, darker and curlier extending into the the mons pubis

Tanner stage 4 : Adult type of hair but does not typically extends to inner side of the thighs.

Tanner stage 5 : Adult hair type extending even to inner aspects of the thighs

Phase 3 (Growth spurt) :

Girls usually reaches peak height velocity in puberty 2 years earlier as compared to the boys. Growth hormone, insulin like growth factor (IGF-1), and gonadal steroid mainly estrogen plays an major roles. Growth spurts preceeds about one years prior to menarche.

Phase 4 (Menarche) :

This is the first menstrual cycle which follows thelarche by about 2 years. The initial menstrual cycles are anovulatory, this is due to the immature HPO axis which may take 1 -5 years to completely mature . Onset of menstruation depends on various factors.

Average age of menarche in India

Study	Age of Menarche
Prabhakar *et al* , 1972	13.2 years
Ghosh *et al* , 1973	13.2 years
Singh *et al* , 1987	13.4 years
Grover *et al* , 1989	12.6 years
Hedge *et al* , 1990	13.5 years

Phase 5 :

This is includes complete sexual maturity with ovulatory menstrual cycle , full breast development and adult pattern of pubic and axillary hair and complete pubertal growth.

PHASE	DESCRIPTION	MEAN AGE(INDIAN STANDARD)
I	Thelarche	10-11 yrs
II	Adrenarche	11-12 yrs
III	Growth spurt /Peak growth velocity	12-13 yrs
IV	Menarche	11-14 yrs
V	Mature sexual hair and breast	14-15 yrs

GONADAL DEVELOPMENT AND FUNCTION

During fourth and fifth month of fetal life, there is appearance of primordial follicles. It constitutes the life long store of follicles for an individual. Thereafter, these follicles grow and enters the antral stage , but before menarche they undergo the process of atresia . During puberty, follicular growth occurs and forms oocytes which enlarges and forms granulosa cells. These follicles undergoes luteinisation during the

reproductive life, forming corpus luteum. It is the main source of gonadal steroids after ovulation. In the absence of fertilization, these follicles undergoes dedifferentiation and cytolysis.

Ultrasonographic studies show that during the pubertal growth, there is an increase in the corpus of uterus form an initial tubular form to bulbous form. There is increase in the length of uterus from 2-3 cms to 5-8 cms. After the onset of puberty, there is increase in ovarian volume from 0.7-0.9 ml to 2-9 ml. According to **Yen SSC in 1980,** " normal ovarian volume is 4 ml in age group of 12-20 years and around 7.5 ml in 20-32 years age".

CONTROL OF GROWTH SPURT IN ADOLESCENT

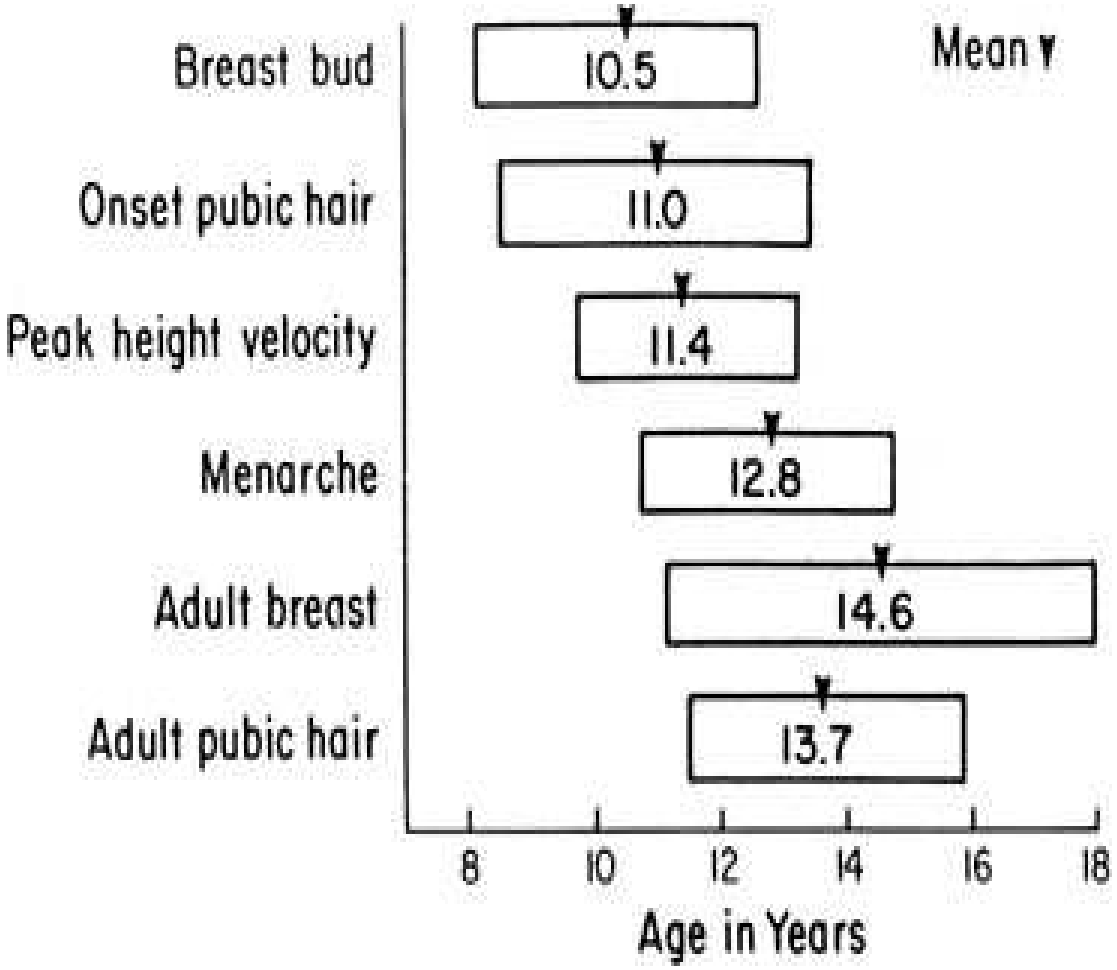
The greatest growth occurs in infancy, thereafter it reduces to minimal till the beginning of puberty. During puberty, a significant proportion about 17-18% gain in the adult height **(Leon Speroff & Marca Fritz, 8th edition 2011).** Growth in puberty is controlled by complex hormonal mechanism involving growth hormone ,insulin like growth factor, gonadal steroids and thyroid hormones.

a) The most important decisive factor of pubertal growth rate is the rate at which circulating GH level increases. GH acts by secretion of IGF-I ,which promotes growth and differentiation.

b) Gonadal steroid act via induction of GH secretion and limiting the adult height by stimulating epiphyseal fusion.

Marshall and Tanner (1969) showed that the mean age for attaining peak height velocity in girls was between 12-14 years.

SEQUENCE OF PUBERTAL MILESTONES



BEHAVIOURAL CHANGES OF PUBERTY :

Adolescence is a difficult time for both the child as well as parents as it involves not only profound physical changes but also triggers emotional, cognitive, and behavioural changes **Patton and Viner 2007.** This alternation in the cognitive processing clearly are associated with change in attitude of adolescents to not only themselves but also towards others. The psychosocial changes during puberty predispose to increased incidence of depression, twice more common in girls as in boys.

HORMONAL AND METABOLIC CHANGES IN PUBERTY :

Puberty is the stage which extends from sexual differentiation and the ontogeny of the hypothalamic- pituitary- gonadal axis to completion of the sexual maturation. Development of hypothalamic-pituitary- portal venous axis results in dramatic rise in FSH and LH in fetal pituitary gland, but it falls around term due to negative feedback effects of estrogen and progesterone derived from placenta. It remains suppressed in early infancy. This pre-pubertal pause lasts about approximately one decade. The HPO axis in girls develop in two distinct stages during puberty:

1) Gonadal steroid dependent negative feedback mechanism
2) Intrinsic CNS inhibitory mechanism.

COMMON PROBLEMS ASSOCIATED WITH PUBERTY

1) **Delayed Puberty :**

   Delayed puberty in girls may be defined as the absence of physical manifestation of puberty by the age of 13years, or the absence of menstruation by the age of 16 years in the presence normal sexual growth.

   Causes includes:-

   a) Constitutional delay (commonest cause)
   b) Hypogonadotropic-Hypogonadism
   c) Hypergonadism-Hypogonadism (Primary gonadal failure)

Constitutional delay which is by far the most common cause of the delayed puberty is considered to be due to physiological immaturity or functional deficiency of gonadotropin hormone. Such girls frequently give history of delayed menarche in their mother or sisters.

Evaluation of Delayed Pubertal Development:

1) Evaluation starts with careful history taking, which must also includes complete family history. Emphasis should be given on the age at the pubertal milestones in other siblings and also parents too.
2) A thorough physical examination.
3) Bone age measurement.

Laboratory evaluation and Imaging :

1) Measurement of serum FSH, LH, Estradiol, TSH, free thyroxine(T4), prolactin , DHEA-S(wherever indicated).
2) X-ray of bone
3) Karyotype
4) MRI or Cranial CT scan (when indicated)

Treatment:

1) **Reassurance and psychological support** to the girl as well as the parents.

2) **Correct specific cause** if diagnosed such as thyroid hormone supplementation in case of hypothyroidism, dopamine agonist in hyperprolactinemia, neurosurgical procedure in operable cranial tumors etc.

3) **Hormonal therapy** – It promotes the age related secondary sexual development ad also induce growth.

   Oral estrogen 0.25- 0.5 mg is given, increasing gradually at an interval of 3-6 month according to response (Tanner stage, bone age).

Progestin in general is started only after the commencement of menses, or after 12-24 months of estrogen therapy in order to ensure that it does not interfere with the development process of breast. After the accomplishment of breast development and establishment of menstruation, hormonal therapy can be discontinued for 1-3 months at intervals, in order to observe commencement of spontaneous menses , as expected in case of constitutional delay of puberty. Persistent hypogonadism even after age of 18 years suggests congenital GnRH deficiency.

2) PRECOCIOUS PUBERTY:

It is defined as the occurrence of pubertal growth ≥2.5 standard deviations earlier than the average age.It is more common among girls than in boys **(Speroff *et al* 1999).**

Classification:-

a) **Gonadotropin- dependent precocious puberty**- also known as "Central or True Precocious Puberty". It is due to early maturation and activation of HPO axis, and development of both breast and pubic hair. They are isosexual, consistent with the actual gender of the child.

b) **Gonadotropin- independent precocious puberty**- also known as “Peripheral or Pseudo Precocious Puberty”. It is the result of early exposure of sex steroid, independent of GnRH and gonadotropins ending up in early sexual development. They may be isosexual or contrasexual.

Evaluation :

a) Clinical, medical and family history

b) Physical examination including Tanner staging and measurement of bone age.

c) Endocrinal evaluation : Basal gonadotropin level
: Serum LH
: Thyroid function test
: GnRH stimulation test
: Serum estradiol, DHEA-S, testosterone, cortisol in gonadotropin- independent precocious puberty.

d) Imaging : i) MRI brain
ii) Abdominal and pelvic ultrasonography.

Treatment:

The aim of treatment is to slow down the development until the girl is of normal pubertal age, to maximize adult height, and to reduce risk of psychological problems associated with early sexual maturation. Reassurance and psychological support to both the adolescent girl and parents is an important aspect of the treatment.

GnRH agonist therapy is the drug of choice in cases of GnRH dependent precocious puberty **(Michael, Thomas & Robert *et al*).**

MENSTRUAL CYCLES :

Menarche is coined from greek word **'men'** meaning **' moon'** and **'arkhe'** meaning **'beginning'.** The normal menstrual cycle results from complex feedback mechanism involving the hypothalamus , pituitary , ovary and uterus. According to **Zarcharias *et al* (1970)** , regular menstruation was shown to occur little more than a year after menarche. Most of the early menstrual cycles are anovulatory. In **Vollman's series (1977)** , 55% of cycles were anovulatory at gynaecological age 1-2, decreasing to 3% at gynaecological age 11-12. Anovulatory cycles usually persists for 12-18 months but can even prolong for 4-5 yrs after the menarche. There are variation in the interval between periods, their duration and the amount of the blood loss in most of the girls. Such

variation are within the physiological limits and requires basic investigation and proper counseling.

According to **Metcalfal 1988,** " menstrual dysfunction is common in the first 18 months following menarche. As many as 58% of adolescents with gynaecological complaints will present as menstrual disorder **(Dramusic *et al* 1991).**

MENSTRUAL DISORDERS IN ADOLESCENTS :

Types of menstrual disorders

1. Amenorrhoea
2. Dysmenorrhoea
3. Irregular menstrual cycles
    a) Oligomenorrhoea
    b) Polymenorrhoea
4. Menorrhagia

AMENORRHOEA IN ADOLESCENTS :

Amenorrhoea meaning absence of menstruation. It is a symptom, not a disease, having various causes. Any of the following criteria needs to be fulfilled to be evaluated for amenorrhoea as per **Fertility & Sterility, 2006**

a) Absence of menses by age of 13 years in the absence of development of secondary sexual character.

b) Absence of menses by age of 15 years irrespective of presence of secondary sexual character.

c) Absence of menses in a previously menstruated women, for an interval of time equivalent to a total of at least three previously, or 6 month.

First two criteria falls under primary amenorrhoea, while the third one under secondary amenorrhoea.

Etiologies of Amenorrhoea :

Primary amenorrhoea is usually the result of genetic or anatomic abnormality. Etiologies are:-

i) Abnormalities of HPO axis –

- Constitutional delay
- Functional (stress, exercise, anorexia etc)
- Kallmann's syndrome
- Gonadal dysgenesis
- Primary ovarian failure

ii) Chromosomal abnormalities

iii) Anatomic abnormalities- e.g. Imperforate hymen, absent vagina, transverse vaginal septum, MRKH Syndrome etc.

iv) Medical disorders – Chronic illness : Juvenile diabetes
: Tuberculosis
: Thyroid disorders

v) Enzyme deficiency - 5α- reductase deficiency
- 17,20 desmolase deficiency

Secondary amenorrhoea are more commoner than primary amenorrhoea. Causes are divided into:-

i) Hypothalamic dysfunction – Stress, excessive weight gain / loss, tumors.

ii) Pituitary disorders - Cushing's disease, adenomas.

iii) Ovarian disorders – PCOS, Premature ovarian failure.

iv) Uterine diseases – Tubercular endometritis

v) Medical disorders – Thyroid dysfunction, chronic illness

vi) Others – Pregnancy, lactation.

Approach to Patient of Amenorrhoea

1. **History taking :** A thorough history regarding the patient as well as family history should be elicited. It must include girl's menstrual history, physical growth history , previous medical and surgical history, etc.

2. **Physical examination :** Detail examination of patient including the height / weight/ BMI/ Nutrition /anthropometry and growth charts, thyroid, breast (Tanner staging), hair distribution, secondary sexual character ,etc.

3. **Pelvic examination :**
   a) Examination of external genitalia : Tanner staging of pubic hair/ virilization / ambiguous genitalia.
   b) Examination of internal genitalia : Presence or absence of uterus /vaginal septum/ imperforate hymen/absent vagina.

4) **Pregnancy** – to be ruled out
5) **Tuberculosis** should be looked for.
6) **Hormonal evaluation :**

   a) FSH/LH
   b) Serum Prolactin

c) Plasma testosterone

d) DHEAS

e) TSH, T_3 and T_4

f) Serum Progesterone

g) Estrogen

The hormonal tests must be done at an appropriate time of menstrual cycle.

7) **USG :** It is an important diagnostic tool.

Hormonal assessment :

- Serum FSH, LH, estradiol – if low then the cause lies in the pituitary.

- If FSH and LH are high, estrogen is low then –

  a) Evaluate for the bone age, if lower than chronological age, then wait and watch.

  b) Kryotyping to rule out Turner's syndrome.

Treatment:

The main objective of treatment of Primary amenorrhoea is to correct the underlying pathology, if possible, and to prevent complication of the disease process. **ACOG** recommends initial reproductive health visit at 13-15 years of age.

Principles in the management of Primary amenorrhoea :

1. Identification of underlying disease and treating the cause.

2. **Reassurance :**

   Adolescent girls and her parents should be reassured regarding anticipated normal pubertal development in case of delay in both growth and puberty.

3. **Short –term therapy with sex steroids (estrogens)**

   This may be needed in girls with Combination delay of growth and puberty (CDGP) to trigger the onset of puberty.

4. **Induction and maintenance of puberty :**

   To prevent the early epiphyseal clsure and also avoid psychological embarrassment due to the peer pressure, the therapy should be started at 13 years of age.

The starting dose of ethinyl estradiol is 1-2 mg mg/day, gradually increased every 2-3 months. Progestin should be added to either on full breast development or after the break through bleeding occurs.

5) **Growth promoting and potentiating strategies :**

In cases like Turner's syndrome (TS) and Prader-Willi syndrome (PWS) with abnormal physical growth like short stature is managed with growth hormone therapy. And to assure maximum gain in height, estrogen replacement therapy can be timely added for optimum synergistic action and preventing early epiphyseal closure.

6) **Prevention of osteoporosis :**

Adolescence is a critical period of bone acquisition depending on nutrition, lifestyle and estrogen. Girls with permanent gonadal failure need estrogen for not only for maintenance of puberty but also for prevention of osteoporosis.

7) **Fertility :**

With newer advancement in the reproductive medicine, a large number of patients with pubertal disorders have been assured of future fertility. Some of the ways are :-

- Induction of ovulation with gonadotropins - in hypogonadotropic hypogonadism
- ART with donor eggs – in hypergonadotropic hypogonadism
- Trans-sphenoidal surgery – in Pituitary adenoma
- Bromocriptine – Hyperprolactinemia
- Mullerian agenesis – IVF with surrogacy using woman's own egg and husband's sperm.

DYSMENORRHOEA :

Dysmenorrhoea is a gynaecological medical condition which is characterized by severe uterine pain during menses. In around 5-10%. It is severe enough to unable them to attend their normal day today work, attend school or college **(Sheil & Turner 1996).** This kind of dysmenorrhoea may lead to fear psychosis in adolescents **(Dickens 1974).**

Study by Sheil & Turner, 1996 says 20% of these adolescents have a family history of dysmenorrhoea either in their mother or sister.

Dysmenorrhoea can be mild, moderate, or severe depending upon the severity, or can be of primary or secondary type depending upon the cause. General measures like counseling and reassurance, lifestyle

modification are the simple measures to overcome this problem. Complete history taking is the most important aspect in the management of such cases, includes details about the menses and associated problems. But depending upon the severity and associated underlying cause if needed, to be treated by pharmacological or surgical management.

Diffentiating features between Primary and Secondary dysmenorrhoea

Features	**Primary**	**Secondary**
Onset	First day of menses	Prior to to menses
Duration	12-24 hours	Throughout the menses
Ovulation	Present	Absent
Pathology	Usually absent	Uterine/ pelvic pathology present
Aetiology	Increased PGE_2 & $PGF_{2\alpha}$	Congestion
Prevalence	Most common	Less common
Severity	In 5-10%	Not so severe

IRREGULAR MENSTRUAL CYCLE

Menstrual irregularities are the commonest gynaecological complain in adolescents **(Dramusic *et al* 1991).** In about 95% of

abnormal vaginal bleeding, the cause is dysfunctional uterine bleeding. DUB is a subset of AUB which is defined as excessive, prolonged,or unpatterned bleeding from the uterine endometrium without an organic cause. These complains varies from excessive bleeding that is regular (menorrhagia), irregular (metrorhagia), combination of both (menometrorrhagia) intermittent or sparse cyclical bleeding (oligomenorrhoea). The treatment of these disorders varies from mere observation to pharmacological and/ or surgical management. About 45% of adolescent girls have an anovulatory cycles for approximately 1-2 years after the onset of menarche **(Sheil & Turner 1996)**, which leads to irregular menstrual cycles. There are mainly two types of irregular cycles:

a) Oligomenorrhoea

b) Polymenorrhoea

OLIGOMENORRHOEA :

Oligomenorrhoea is infrequent menstruation. It is defined as the periods occurring at a interval of more than 35 days for atleast 6 months in a previous normal cycle.This in adolescents are commonly due to anovulation but if the history and clinical examination is suggestive of any organic cause further evaluation may be required.

Causes of Oligomenorrhoea :

a) Emotional stress and exercise

b) PCOS

c) Thyroid dysfunction

d) Anorexia nervosa

e) Adrenal hyperplasia

f) Pituitary tumors

g) Excessive weight loss

h) Obesity

Treatment :

1) **Reassurance :**

Adolescents and also their parents needs to be counseled properly regarding the problem and reassured that this is usually self limiting and this is not going to affect their fertility in future, if no pathological cause is observed.

2) **Hypothalamic or Pituitary causes :**

Due to the rise of expectation from parents , society and peer pressure these adolescents are in constant physical and psychological stresses leading to defect in pulsatile secretion of GnRH, which inturn ends up in oligomenorrhoea. So, this can be

managed with proper counseling and behavioral therapy. No drugs are required for regularization of menstruation.

3) **Hyperprolactinaemia :**

Hyperprolactinaemia in adolescents is rare but if present can be treated with medical drugs like cabergoline, bromocriptine and definitive surgery for prolactinomas, if diagnosed.

POLYCYSTIC OVARIAN SYNDROME (PCOS)

Hyperandrogenism is a frequent cause of oligomenorrhoea in adolescence. The most common form is the syndrome of PCOS. PCOS is a heterogenous disease . It requires special mentioning because they are common in adolescent population.

Several studies have been performed regarding pathophysiology of PCOS but till date no final consensus have been agreed although recently familial clusters of PCOS is reported- suggesting a major component of its etiology**. Steven Frank study** suggests the involvement of two key genes in the etiology of PCOS , the steroid synthesis gene CYPIIa and insulin gene- Variable number tandem repeats (VNTR).

PCOS comprise of a wide spectrum of signs which ranges from presence of multicystic ovarian morphology detected by USG, to obesity ,

menstrual irregularities, infertility and to even cardiovascular disorders – all due to metabolic disturbances involving increased level of LH, insulin and androgen and dyslipidemia.

Pre-pubertal ovaries are usually multicystic. These multicystic ovaries are normal findings in the evolution of mature hypothalamic-pituitary-gonadol axis, as described by **Merrill.**

Therefore, PCOS is defined as a dysfunctional condition of the ovary in which there is increased LH dependent secretion of androgen from hyperplastic theca and stromal cells of ovary.

Clinical features of PCOS :-

a) Hirsutism
b) Menstrual irregularities
c) Central obesity
d) Infertility
e) Pelvic examination(if done) – often normal, as it is uncommon to palpate enlarged ovaries in teenagers.

Rotterdam criteria (2003) suggests presence of at least two criteria to be diagnosed as PCOS, these criteria are :-

i) Oligo/ amenorrhoea, anovulation, infertility

ii) Hirsuitism

iii) USG features of PCOS as described above.

Laboratory Findings :

Endocrinal Screening :

Prolactin and TSH levels are tested to rule out pituitary or thyroid disease as an etiology of anovulation.

In PCOS there is –

- Normal or increased LH
- Normal or increased 17 ketosteroid
- Normal or increased FSH
- Normal or increased E2
- Increased LH/FSH ratio

Sonographic Findings:

Typical USG findings in PCOS

i) No. of cyst = >10mm pushed periphery (Necklace pattern)

ii) Abnormal stroma

iii) Uterine width : ovarian length=<1,

iv) Increased ovarian volume(> 10 ml),

v) Increased ovarian roundness index=>0.7

Ovarian Histology :

Multiple microcysts with atretic and immature follicles , fibrosis thickening , and sclerosis of ovarian capsule.

Treatment : Depends on various factors such as :

- Age of girl
- Presence or absence of acne, hirsutism , obesity
- Menstrual irregularities
- Presence or absence of hyperinsulinemia or hyperandrogenism or high LH
- Prevention of long-term sequelae.

The purpose of treatment is to-

- Treat menstrual irregularities
- Treat hirsutism
- Treat infertility
- To prevent long term consequences of PCOS.

Thus, the treatment is modified or prescribed as per the requirement of women. It is subdivided into:-

a) Life style modification
b) Medical management
c) Surgical management

Lifestyle modification :

It include weight reduction, exercise, low calorie diet intake, abandoning cigarette smoking etc. Weight reduction has beneficial effects on menstrual abnormalities as well as in hirsutism **(Guzick, Wing, Berga *et al* 1989)**. Studies have shown reduction in the level of (a) Serum free testosterone (b) Insulin and insulin like growth factor I(IGF-I) and (c) increase in the level of SHBG due to intake of very low energy diet in girls with PCOS . It has been shown that weight reduction decreased

ovarian P450c17a activity and cause decrease serum free testosterone level in obese girls with PCOS.

Weight loss causes for decrease in both hyperinsulinemia and insulin resistance, increases SHBG and thus results in overall reduction in hyperandrogenism.

Medical Management :

Most commonly used are metformin which reduces hyperinsulinemia and hyperandrogenism independent of changes in body weight (obesity) and OCPs for regularization of periods. The usual dose of metformin is 500 mg thrice daily and can be gradually increased if required. But girl should be cautioned that it make take 6 months or more for complete results. And, patients should also be cautioned that it may recur, later in reproductive life.

Surgical Management:

Surgical management is reserved only in following cases: -

- Medical therapy fails
- Hyperstimulation following medical treatment
- Infertility
- Previous pregnancy loss

Surgical procedure comprises of :-

a) Wedge resection of ovary

b) Laparoscopic ovarian puncture- for not more than four cysts in each ovary either by laser or by unipolar electrocautery.

But these surgical procedures have disadvantages of forming pelvic adhesion postoperatively which may further add on to reduction in fertility rate.

SEQUELAE OF PCOS

Long- term sequelae in PCOS is important to know because mainly two reasons:-

- Higher incidence of PCOS in adolescent (20%) diagnosed by USG
- Because of its impact on the future reproductive life.

Complication of PCOS

a) Short- term sequelae –
   i) Obesity
   ii) Hirsutism
   iii) Menstrual irregularities
   iv) Infertility

b) Long- term sequelae

i) Diabetes

ii) Cardiovascular disease

iii) Osteoporosis

iv) Cancer

POLYMENORRHOEA

Polymenorrhoea is the least common menstrual complaint in this age group. It is usually caused by luteal phase defect (LPD). Adolescents with such complaints are treated with progesterone support in luteal phase. OCPs are used to regularize the cycles.

PUBERTY MENORRHAGIA

Puberty menorrhagia is the excessive menstrual blood loss between menarche and 19 years of age. Menorrhagia is defined as menstrual loss greater than 80 ml. Anovulation and bleeding disorders make up the vast majority of menorrhagia in adolescent. In adolescents, the HPO axis takes time to mature after menarche, which can lead to anovulation.

In first 2 years after menarche, 55-82% 0f cycles are anovulatory, and by fourth and fifth year this decreases to 20% of cycles being anovulatory. These patients generally lack the positive feedback

mechanism necessary to initiate an LH surge and subsequent ovulation despite increased follicular estrogen levels. But, the negative estrogen mechanism is intact in these patients. These are hypothalamic problems rather than pituitary as indicated by normal GnRH stimulation. Unopposed estrogen stimulates endometrial growth, which ultimately outgrows its blood supply. The endometrium becomes excessively thickened and unstable , and the lining breaks down irregularly and unpredictably. This leads to heavy bleeding and prolonged menstruation.

Causes of Puberty Menorrhagia :

- Anovulatory uterine bleeding
- Coagulation disorders
  - Von willebrands disease (32-100%)
  - Idiopathic thrombocytopenic purpura
  - Platelet disorder-e.g. Bernard –Soulier Syndrome (51%), Glanzmann's thrombasthenia(98%)
- Endometrial tuberculosis
- Thyroid dysfunction
- Pregnancy (In cases of heavy bleeding, adolescent pregnancy should always be ruled out.)

History & Physical Examination:

The evaluation of the adolescent with menorrhagia should begin with detailed history. It is important to assess family history for presence of any known bleeding disorders. Upon physical examination, height, weight, BMI, orthostatic blood pressure and pulse should be recorded. Examination of major body systems gives insight to endocrinological or systemic disease.

Investigation :

1) Complete blood count ,
2) coagulation profile (bleeding time, clotting time, PT, ApTT),
3) Thyroid function test(TSH ,FT4,FT3)
4) Ultrasonography of pelvis are useful parameters.

If history indicates a bleeding disorder, if bleeding is severe, prolonged or associated with menarche, or if initial screening is abnormal, specific laboratory test for coagulation defects should be done. In developing countries like of ours, where tuberculosis is still highly prevalent, it is a routine test to rule out tuberculosis by laboratory tests like montoux, chest X-ray, and even TB-PCR of the first day menstrual blood.

Treatment :

The goal of initial assessment is to determine which adolescent needs treatment and which adolescent can be observed until the maturation of HPO axis results in regular normal menses.

1) **Counseling and reassurance** - In most of girls this is the only therapy required.

2) **Anaemia** is corrected with iron supplementation and high protein diet and if required blood transfusion is suggested.

3) **NSAIDS** like mefenamic acids, antifibrinolytic such as tranexamic acid and aminoaproic acid , can reduce menstrual blood loss by 50%.

4) **Acute bleeding** is stopped by 5-10 mg of norethisterone medroxyprogesterone orally. Later on, cyclic progesterone therapy is recommended

5) **Hormonal therapy**: Hormonal therapy is the most effective therapy, with more than 93% of adolescents responding to some form of hormonal treatment. Indication for start of hormonal therapy are as follows:-

a) Anaemia

b) Recurrence

c) Restricted routine activities

The initial treatment is the use of oral medroxy progesterone acetate followed by the use of combined oral contraceptive pills. OCPs can also be used as a first line of treatment in treating menorrhagia in adolescents with bleeding disorders.

If OCPs are contraindicated, or the patient or family does not wish to start oral contraception, cyclic progestins can be used.Oral medroxyprogesterone acetate 5mg can be given for 10-14 days or 21 days each month to induce a withdrawal bleeding that is cyclic and predictable. This pattern is continued for 3-6 months.

6) **Diagnostic curettage (Sheil & Turner 1996)** is rarely indicated in non responder to hormonal therapy in these age group patients. If endometrial hyperplasia is seen then she is put on progesterone for a period of 6-12 months, after which she re-evaluated.

   Careful assessment and prompt recognition is important in the adolescent with menorrhagia. No single therapy or treatment is universal, and it must be tailored to the adolescent and clinical situation.

INFECTION IN ADOLESCENT :

Due to lack of oestrogen and alkaline vaginal secretions, young girls are more prone to infection in the pre menarche period . Vaginal discharge is generally the result of infection caused by non specific causes, resulting from poor hygiene or as a result of specific infection.

Aetiology :

1) **Chemical / Irritant (or Allergic)**

2) **Poor hygiene :**

   Poor personal hygiene may lead to candidal vulvovaginitis, vulval irritation may follow worm infection like pin worms , thread worms secondary to anorectal contamination.

3) **Infection** :

   Infection of vulva and vagina i.e, vulvoginitis most commonly due to the infection caused by the normal vaginal flora, which includes mixed aerobes and anaerobes, commonly staphylococcus epidermidis, lactobacilli, bacteroides etc. Sexually transmitted infections like that caused by Neisseria gonorrhoea, Chlamydia trachomatis, Trichomonas vaginilis.

4) **Foreign bodies**

5) **Sexual abuse**

Diagnosis :

a) Detailed history including sexual ativity, type of discharge, use of antibiotics, concomitant infection elsewhere in body, treatment taken etc.

b) Clinical examination – with utmost care. P/R Examination may be required.

c) Vaginal or urethral discharge collected and wet smear examined in microscope.

d) Examination under anaesthesia may be required if suspicion of foreign body in vagina or foul smelling discharge is present.

Management :

- ✓ Appropriate antibiotics for specific organism.
- ✓ Non specific Infections : improve hygiene of private parts. Local application of estrogen cream 0.10% for 2-3 weeks.
- ✓ Specific infections : Trichomoniasis : Metronidazole 20 mg three times a day for 7 days Alternative single dose of 2 gm of metronidazole.

- ✓ Candidiasis : Oral nystatin 5 lac units three times a day for two weeks or oral fluconazole. Locally clotrimazole or miconazole cream for 6-12 days.

OVARIAN MALIGNANCIES IN ADOLESCENT :

Total incidence of ovarian cancer in adolescents ranges from 95 to 225 per million person years and highest being recorded in Australia and Israel, and lowest in India and Japan.

Ovarian neoplasm accounts for approximately 1% of all malignant tumors in girls aged 17 years or below **(Young & Miller, 1975).**

Ovarian masses may be of benign or malignant. Dealing with ovarian tumors in adolescents is particularly a challenge because of its rarity, atypical symptoms, malignant potential, and probable serious outcome on the patient's reproductive life.

Functional ovarian cysts are the most common benign ovarian masses detected in adolescents. Amongst all age group, adolescents have the highest rates of PID which pre-disposes them to develop tubo-ovarian abscess. As far as true ovarian tumors are concerned , they

comprise 1.5% of all adolescent tumors with an absolute incidence of approximately 5.5%.

Clinical Presentation :

Ovarian neoplasia are known for their silent presentation and detected mostly as an incidental finding. Commonest presentation will be the complain of only vague abdominal discomfort or bloating sensation which is invariably treated with antispasmodics and antiflatulents. The presenting complaints are pelvic pain, pressure symptoms on bladder or rectum, menstrual irregularities etc. The vast majority of children with malignant ovarian tumors are detected at an advanced stage as in majority of cases it doesn't show symptoms till it reaches advance stage. However it has now become clear that ovarian neoplasms also cause particular symptoms in particular stages of disease progression. Keeping this fact into mind, Symptom index has been developed for screening of ovarian cancer is under trial in USA. Torsion may occur in as many as 35 to 45% of ovarian tumors in adolescents. These cases are wrongly diagnosed as suffering from appendicitis. The use of imaging modalities such as X- ray and ultrasound will increase the diagnostic accuracy to 80%.

According to National Cancer Institute's SEER program, cancer statics review(1973-1988), the most common tumors in

adolescent females (15 -19 years) are germ cell tumors (15%). Dysgerminoma are the most common malignant germ cell tumors, which account for about 30-40% of all ovarian cancers of germ cell origin. Dysgerminoma destroy the ovarian tissue may cause amenorrhoea which must be differentiated from tuberculosis which often presents as an abdominopelvic mass due to encysted ascites.

Endodermal sinus tumor of ovary are also common germ cell tumor seen in paediatric and adolescent age group. They grow rapidly and present usually as abdominal or pelvic pain or abdominal enlargement. Asymptomatic pelvic pain is seen in 100%. Granulosa cell tumors present as precocious puberty in young adolescent or as abnormal vaginal bleeding in the older adolescent. It accounts for about 1-2% of all ovarian malignancies.

Investigation :

Baseline investigation should always include pregnancy test regardless of elicited sexual history. USG, CT Scan, MRI forms the cornerstone for evaluation of the exact size, location, internal consistency, relationship with other structures and also spread to other organs (metastasis). Chest radiograph should be done. Abdominal X-ray for visualizing calcifications in teratomas.

Tumor markers are an important laboratory investigation which are extremely useful in monitoring ovarian neoplasms. CA 125, alphafetoprotein, human chorionic gonadotrophins(HCG) are such tumor markers which are elevated in specific malignancies. CA125 is elevated in epithelial tumors . HCG and alphafetoprotein are raised in endodemal sinus tumor and non gestational choriocarcinoma.

Management :

The main aim of management of ovarian tumor is to conserve the reproductive potential without jeopardizing her life. Asymptomatic cystic adnexal masses requires only observation as these are always benign and regress spontaneously in 3-6 months or promotes regression with oral contraceptives for 3 months.

Surgery is indicated in following conditions :

- Ovarian cyst > 6 cm without regression for 6-8 weeks
- Any cystic lesion > 10 cm
- Solid ovarian lesion
- Ovarian lesion with papillary excrescences in its wall
- Bilateral
- Presence of ascites

Usually cystectomy is the choice of surgery in order to preserve her reproductive potential. Benign conditions should be managed by conservative surgery either by laparoscopy or laparotomy. Surgery like salphingo oopherectomy is consider in cases associated with torsion and infarction.

Endometriosis in adolescent is managed primarily by non surgical methods and includes prolonged suppression of ovulation. Mature cystic teratomas are managed surgically by only removal of the affected gonad with preservation of ipsilateral tube. In case of teratomas, close inspection of the contralateral ovary should be done for evidence of bilateral disease.

Fertility preservation surgeries in adolescent girls:

Preservation of fertility in adolescent girls has been a matter of great concern for the gynaecologist dealing with them, at the risk of ovarian damage. In adolescent girls, fertility may be impaired by repeat ovarian surgeries ,use of gonadotoxic treatment or genetic disorders. In recent times, various options have emerged in order to preserve fertility in teenage girls like cryopreservation of embryos, mature and immature oocytes and ovarian cortex prior to use of gonadotoxic therapy.

Cryopreservation of ovarian tissue has been proposed for adolescent girls suffering from Turner's syndrome, especially the mosaic type.

Treatment of cancer in adolescents should be a multi-disciplinary settings and is based on the degree of malignancy. The primary treatment is surgery with proper staging. In advanced cases of malignant germ cell tumor , which is associated with metastasis, ascites etc surgery is followed by post operative radiation therapy as these tumor are radiosensitive. But the major disadvantage of radiation therapy is the loss of fertility. So, now the treatment of choice is the combination chemotherapy eg. BEP,VBP,VAC.

Adolescents treated for ovarian tumors should be closely followed up, particularly if ovarian preservation was attempted. In the follow up, detailed history , thorough clinical examination, USG and specific tumor marker should be done.

Adolescent Sexuality :

Adolescence is a critical time when there is curosity and increase in sexual drive. This time offer an ideal window of opportunity for building the foundation of sexual and reproductive health in adolescents. The burden of adolescent sexual behavior are an enormous burden on both

adolescent and the society. Developmentally, adolescent reaches physical maturity before they are cognitively able to appreciate the consequence of their behavior. A teenager's major source of information regarding sexuality is his or her peer group, all of whom are experiencing and reinforcing the same behaviors. The family, the major socialize of other behaviors is not as powerful a force in shaping responsible sexual behavior because of parental discomfort in sex education and sexual discussion. A healthy attitude towards healthy sexual interaction, and awareness of their behavior and needs, followed by counseling can prevent many traumatic consequences.

MATERIALS AND METHODS

A total of 150 cases of adolescent girls aged 13-19 years who attended gynaecological OPD and emergency department in ISO & KGH hospital, Triplicane were included in the study.

Study Design :

Prospective study.

Inclusion Criteria :

Married / unmarried, non –pregnant, non lactating adolescent girls aged 13-19 years.

Exclusion criteria :

Teenage pregnancy

History :

Detailed history with regard to the gynaecological problems was taken from the patient and girl's mother was also interviewed to get accurate details about any previous medical problems if present.

Physical Examination :

A thorough clinical examination including height, weight, secondary sexual character, general examination of breast, thyroid, cardiovascular system, respiratory, and central nervous system or any congenital anomalies were noted.

Body mass index (BMI) or quetelet index was calculated using the formula:-

$$\text{BMI} = \frac{\text{Weight in kg}}{(\text{Height in cm})^2}$$

General examination comprising thyroid examination, presence of hirsutism, pubertal stage of breast and pubic hair were graded according to Marshall and Tanner staging. External genitalia examined. Per abdominal examination done to rule out any mass. Per rectal and bimanual pelvic examination done whenever indicated.

Then patients were subjected to various investigations like haemogram, coagulation profile, hormonal assays, and ultrasonography depending on diagnosis clinically.

Amenorrhoea cases were referred to endocrinologist and genetic counseling done. For all cases, relevant investigation like karyotyping was done and the diagnosis confirmed. Patients were also referred to haematologist, oncologist in those indicated.

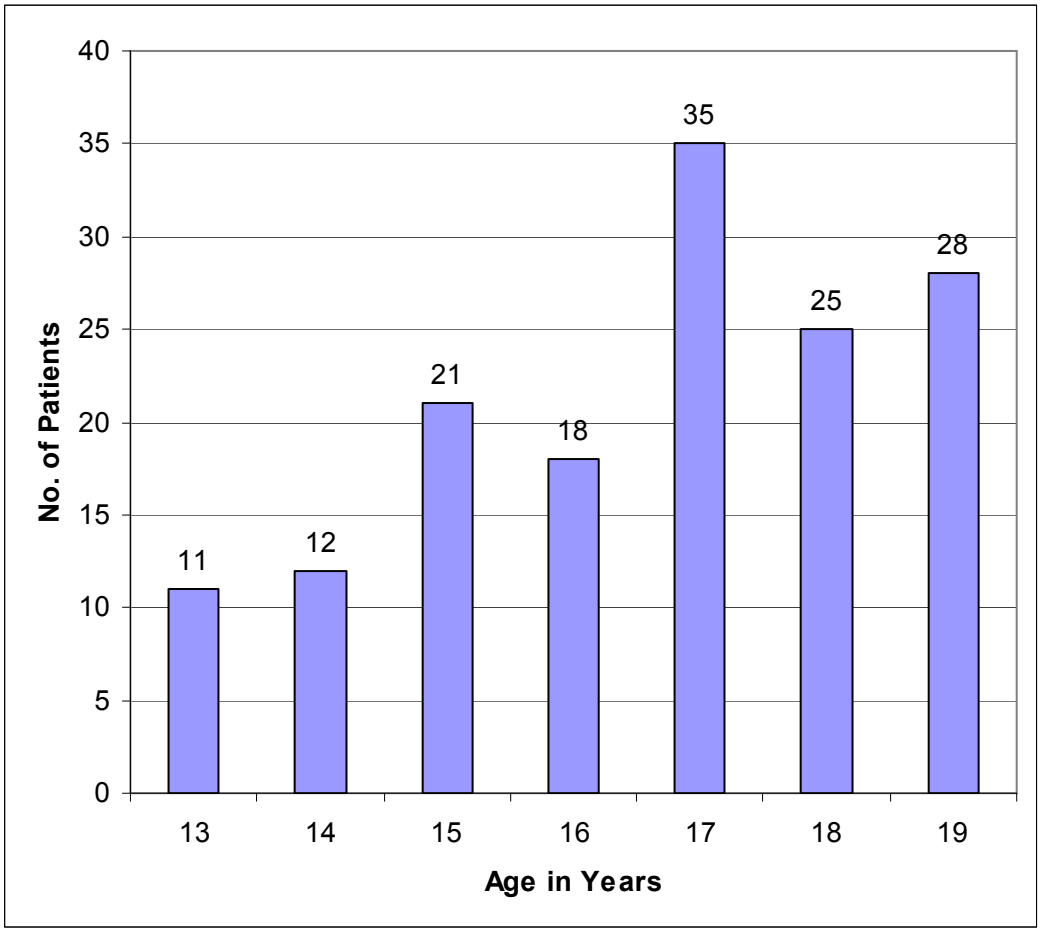
OBSERVATIONS

Table 1 : Age Distribution

Age in years	No. of patients	Percent
13	11	7.3
14	12	8.0
15	21	14.0
16	18	12.0
17	**35**	**23.3**
18	25	16.6
19	28	18.6
Total	**150**	**100.0**

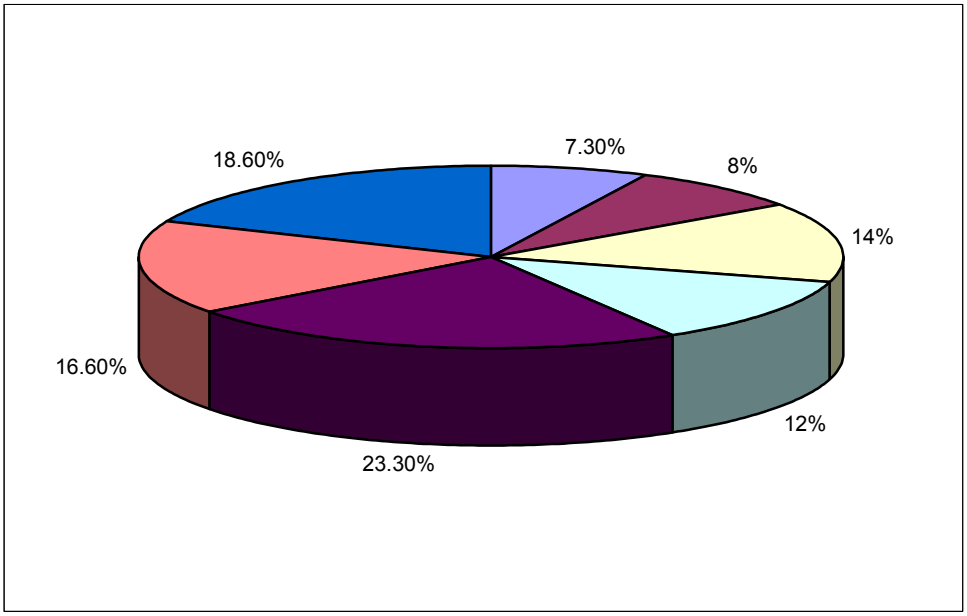
The table shows the age distribution in the study group. It ranged from 13- 19 years of age. Maximum number of adolescent girls attending the gnaecology OPD in KGH were of 17 years of age (3/150), followed by girls with age of 19 years(28/150).

Chart 1 : Age Distribution



This bar diagram shows the diagramatic representation of age distribution among the adolescent girls in the study group. Maximum incidence is of 17 years.

Chart 1 : Age Distribution



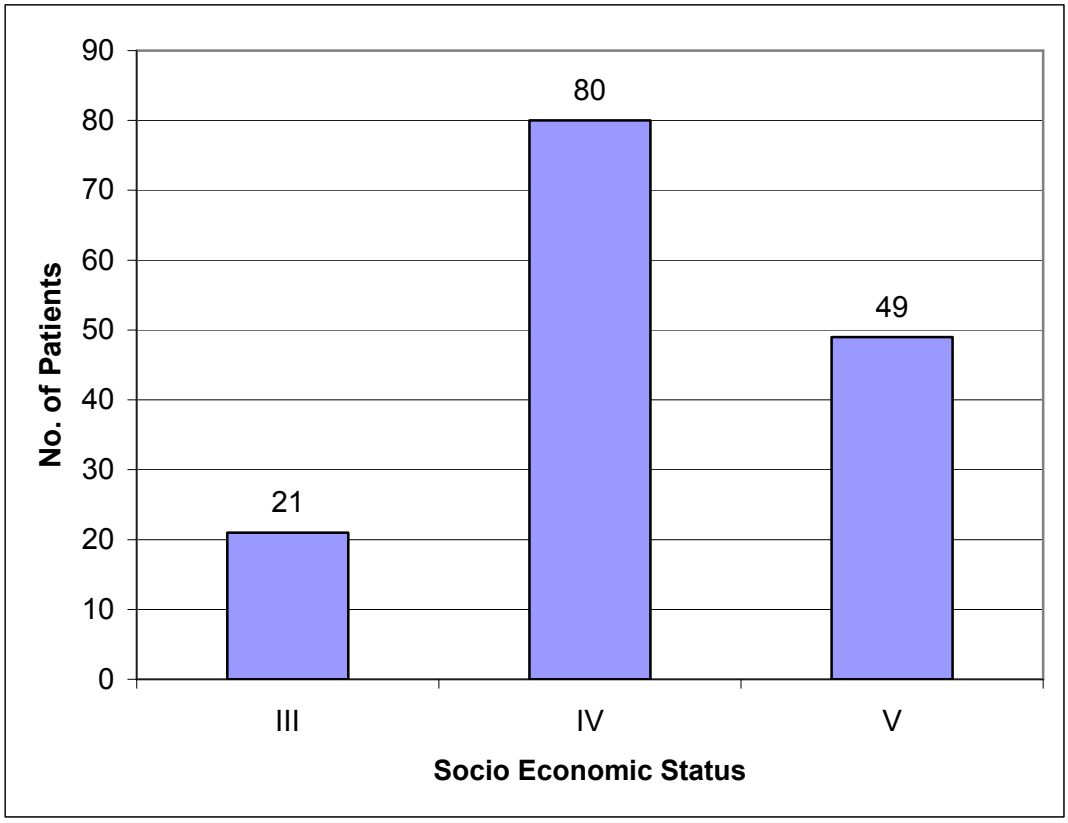
The bar chart depicts that the, adolescent girls of age group 17 years attending Gynaecology OPD were maximum (23.3%).

Table 2 : Socioeconomic status

Socioeconomic Status	No. of Patients	Percent
III	21	14.9
IV	**80**	**53.3**
V	49	32.6
Total	**150**	**100.0**

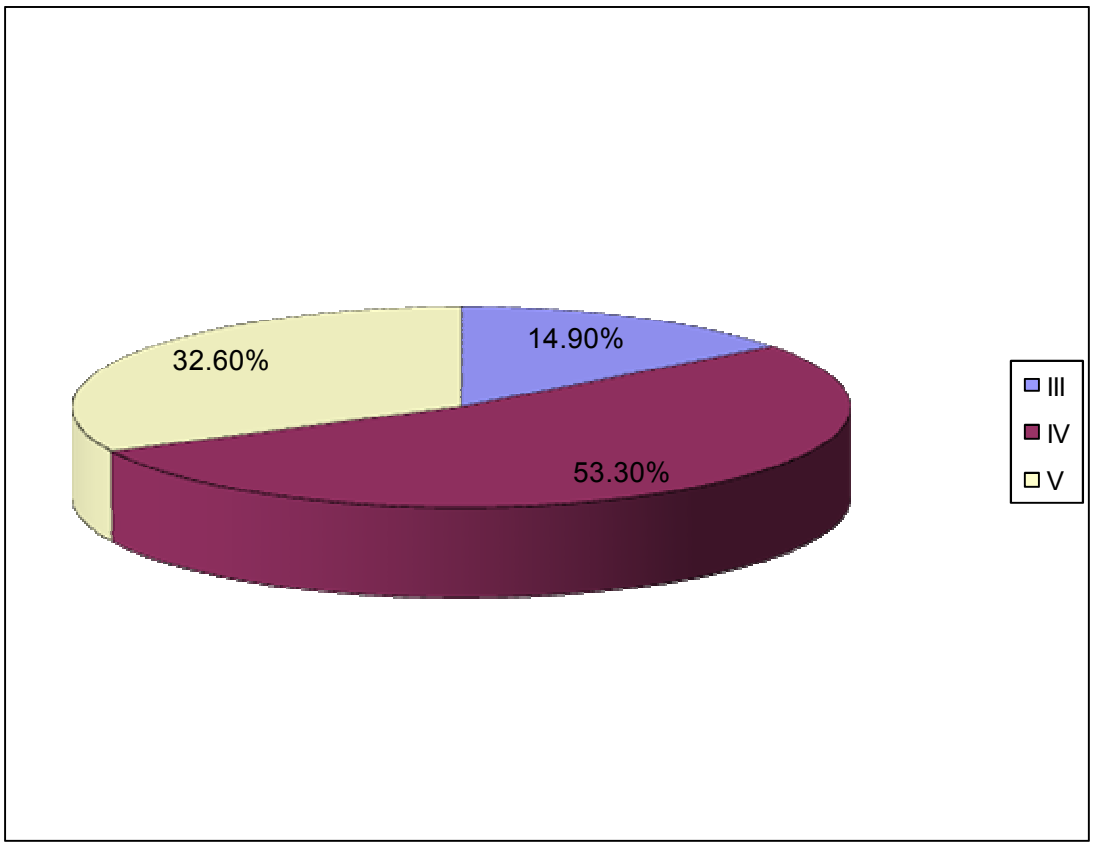
In the present study, all the girls were mostly from family with lower socio economic status either from Class-III / IV / V.

Chart 2 : Socioeconomic status



In the present study majority of adolescent girls came from low socio economic background with highest number of 80 cases under Class-IV socio economic status (80/150).

Chart 2 : Socioeconomic status



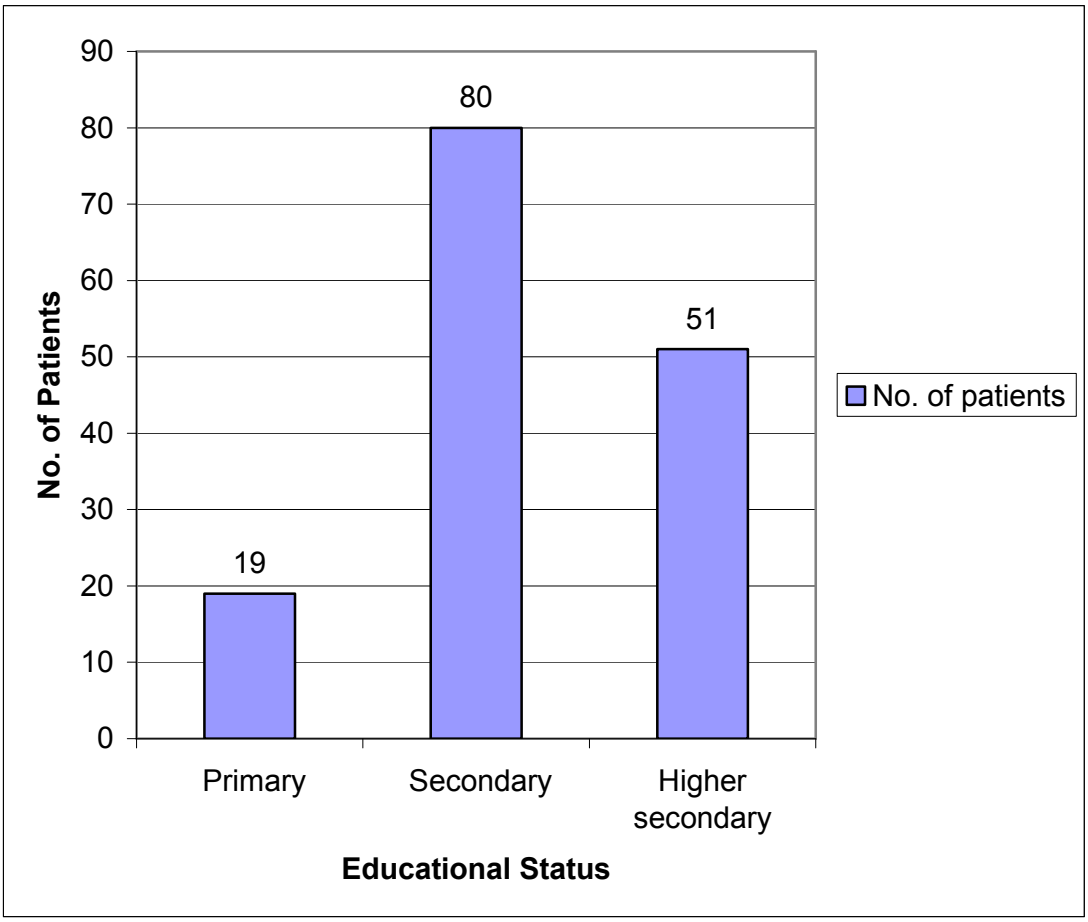
Out of 150 adolescent girls, 14.9% belonged to class III socio economic status, 53.3% belonged to class IV, 32.6% belonged to class V socio economic status.

Table 3 : Educational Status

Education	No. of patients	Percent
Primary	19	12.6
Secondary	**80**	**53.3**
Higher secondary	51	34.0
Total	**150**	**100.0**

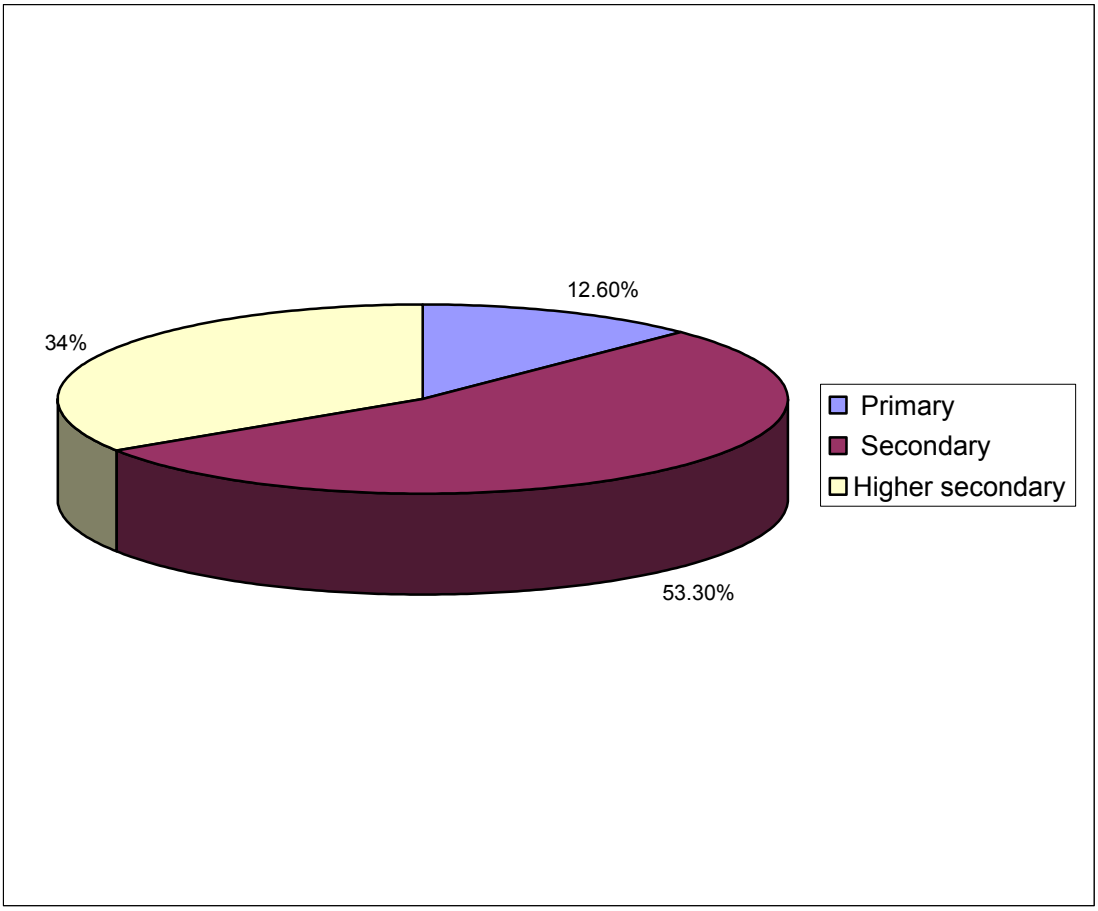
This table shows the number of adolescent girls in the study group with their educational status. Though literacy rate among the adolescent girls was found to be 100 percent, but percentage of school dropouts were 3.33% (5/150).

Chart 3 : Educational status



In the present study, majority of girls were studying in secondary standard (80/150), followed by girls with higher secondary educational status.

Chart 3 : Educational status



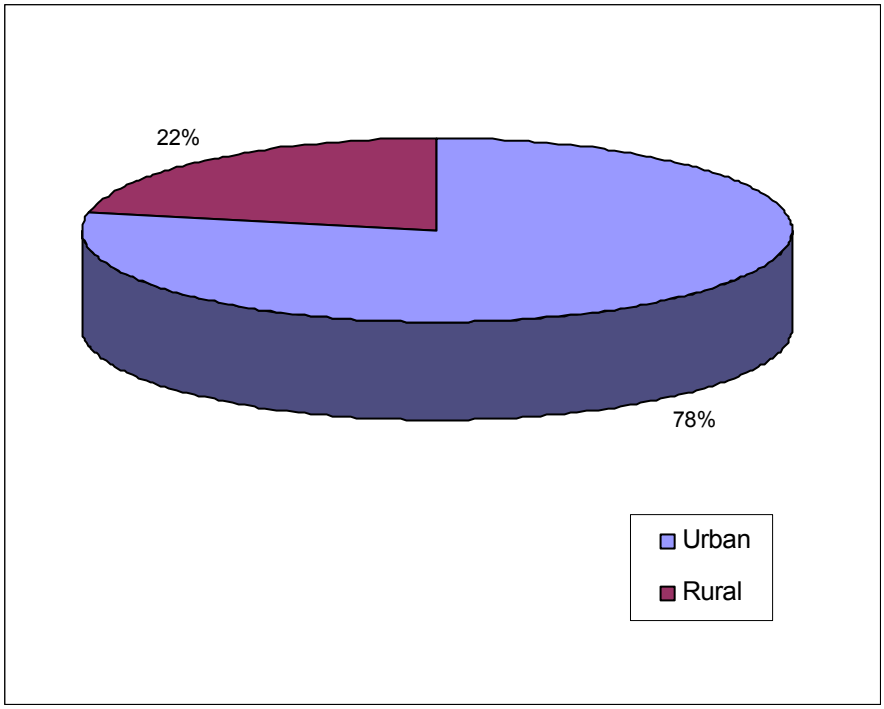
This pie chart represents that maximum percentage (53.3%) of adolescent girls in the present study group were having educational status as secondary standard.

Table 4: Demography

Place of living	No. of patients	Percent
Urban	117	78.0
Rural	33	22.0
Total	**150**	**100.0**

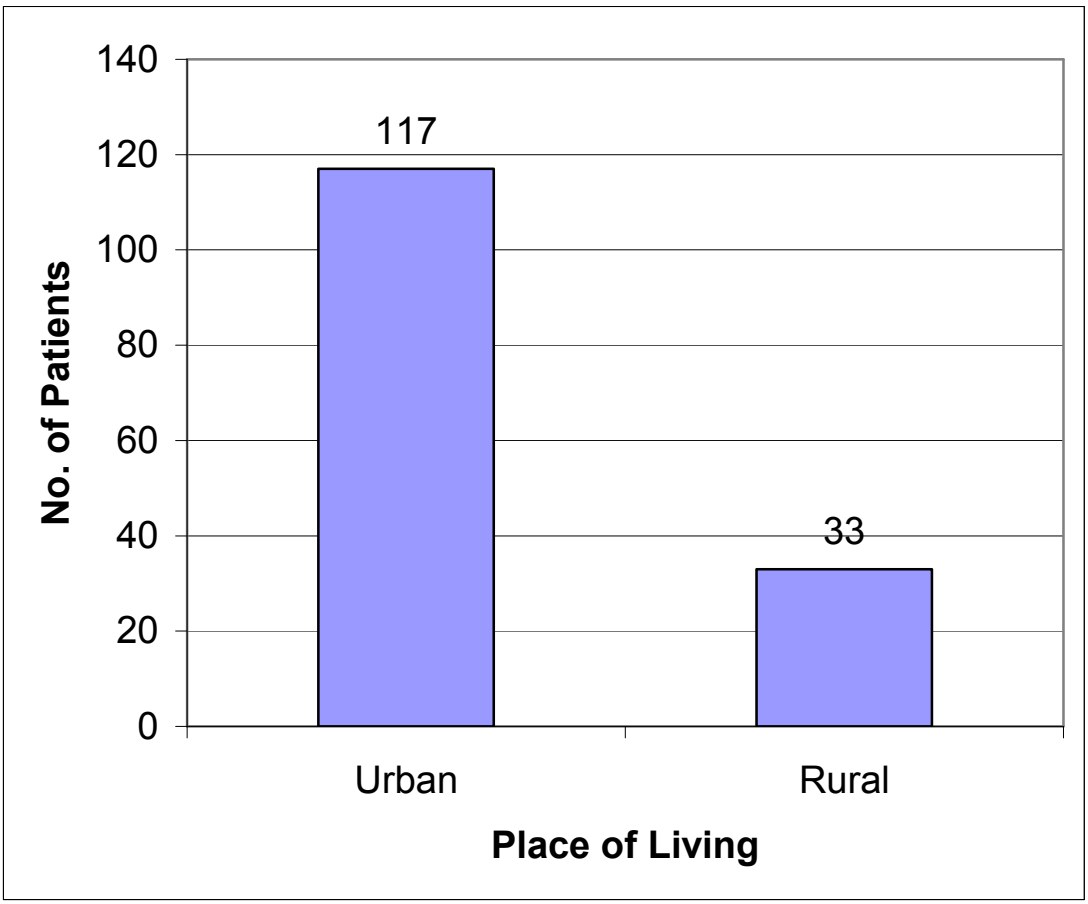
Majority of the adolescent girls under study belonged to urban area (78.0%)

Chart 4: Demography



This pie chart shows that maximum percent (78.0%) of adolescent girls in the study group came from the urban population.

Chart 4: Demography



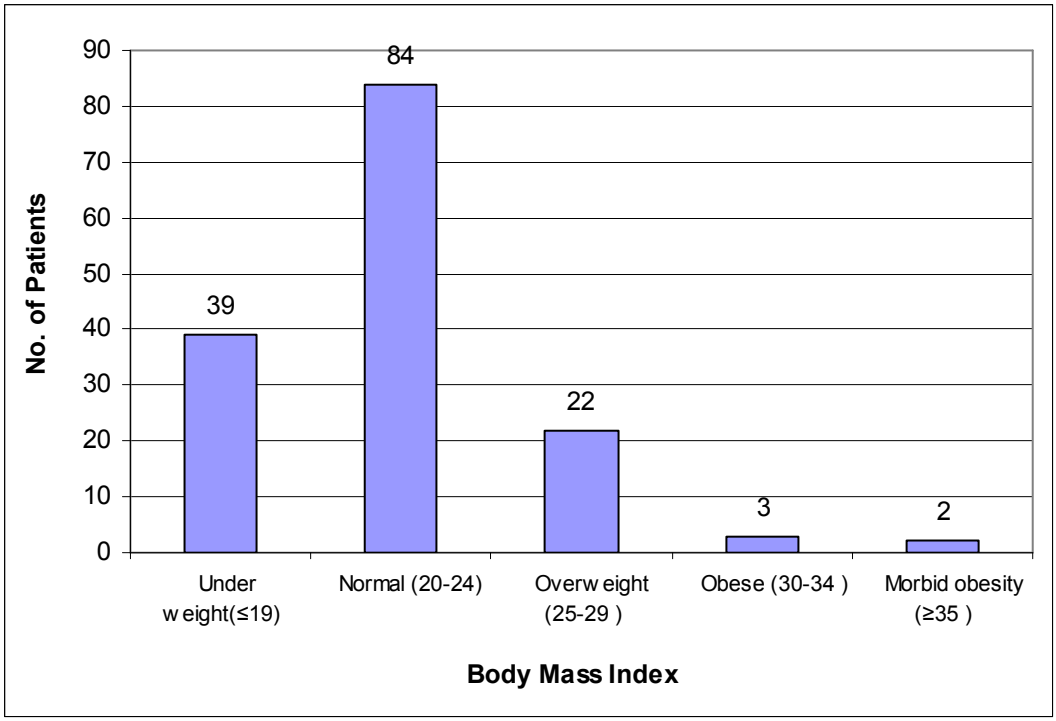
Out of 150 cases studied, 117 girls came from the urban area and rest of 33 girls were from rural area in and around of KGH, Chennai.

Table 5 : Body mass index (BMI)

BMI	No. of patients	Percent
Under weight(≤19)	39	26.0%
Normal (20-24)	**84**	**56.0%**
Overweight (25-29)	22	14.6%
Obese (30-34)	3	2.1%
Morbid obesity (≥35)	2	1.3%
Total	**150**	**100.0%**

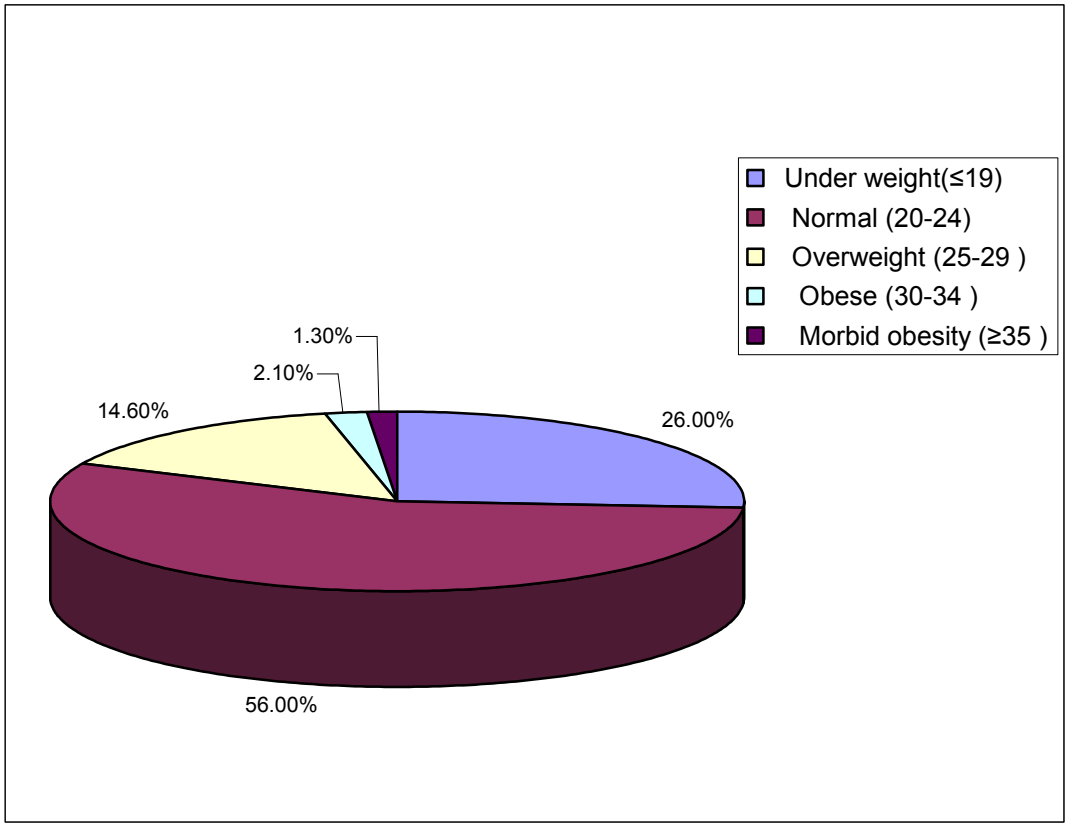
In the study group, adolescent girls were categorized into normal, underweight, overweight, obese and morbidly obese, as per their BMI calculated using weight measured in Kg and height in cm.

Chart 5 : Body mass index (BMI)



Out of total 150 cases of adolescent girls, majority (84/150) were having normal BMI, followed by (39/150) underweight, overweight (22/150). There was only few cases of obesity (3) and morbid obesity (2).

Chart 5 : Body mass index (BMI)



Among the 150 adolescent girls in the study group, maximum percent of girls had normal BMI (56.0%), 17.6% had higher range of BMI while about 26% were underweight.

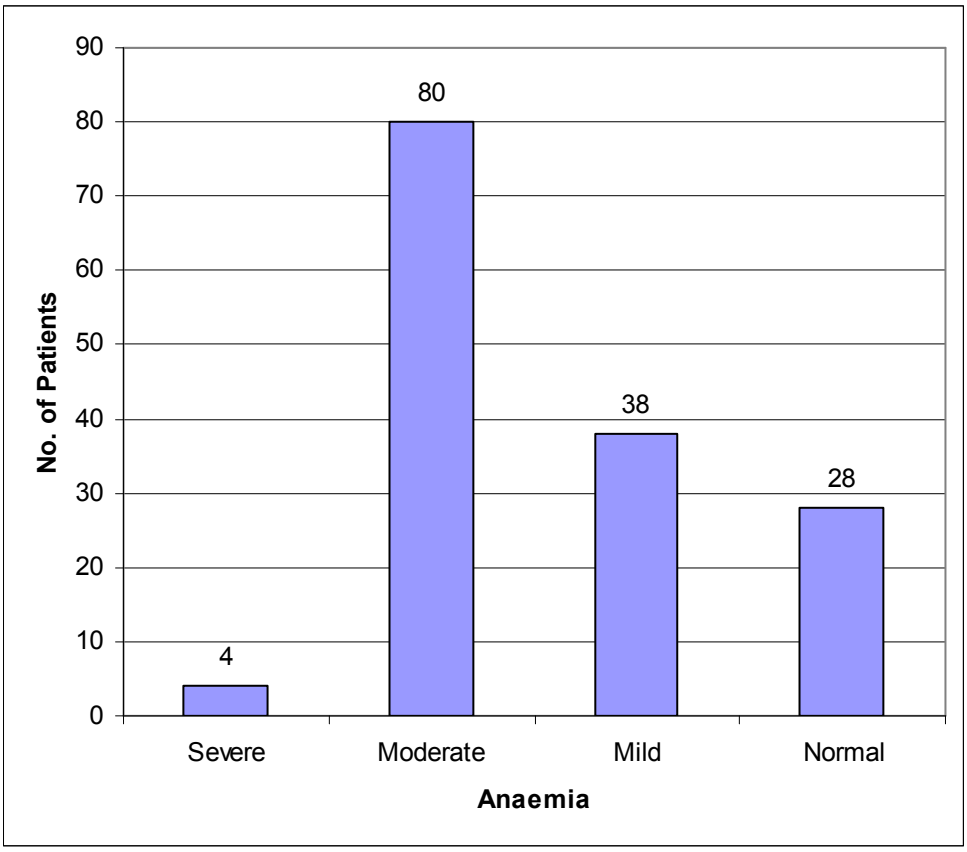
Table 6 : Anaemia incidence (Hb% estimation)

Anaemia	No. of Patients	Percent
Severe	4	2.6
Moderate	**80**	**53.3**
Mild	38	25.3
Normal	28	18.6
Total	**150**	**100.0**

Majority of the adolescent girls under study were anaemic, which ranged from mild to severe type based on the haemoglobin estimation.

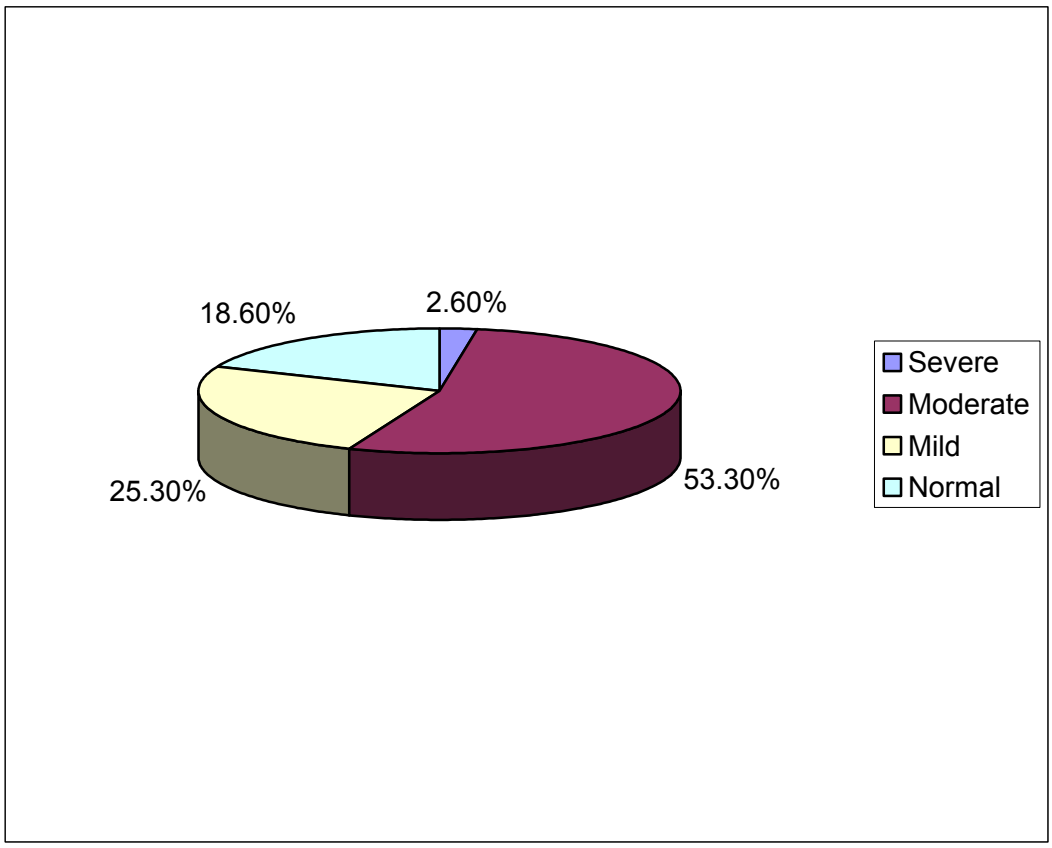
- 28/150 cases had no anaemia with hb% ≥12 gm%.
- 38/150 cases had mild anaemia with hb% ranging from11-11.9 gm%.
- 80/150 cases had moderate anemia with hb% ranging from 8.1-10.9 gm%.
- 4/150 cases had severe anaemia hb% <8 gm%

Chart 6 : Anaemia incidence (Hb% estimation)



Moderate type of anemia with haemoglobin percent ranging from 8.1-10.9 gm% were most prevalent among the study group.

Chart 6 : Anaemia incidence (Hb% estimation)



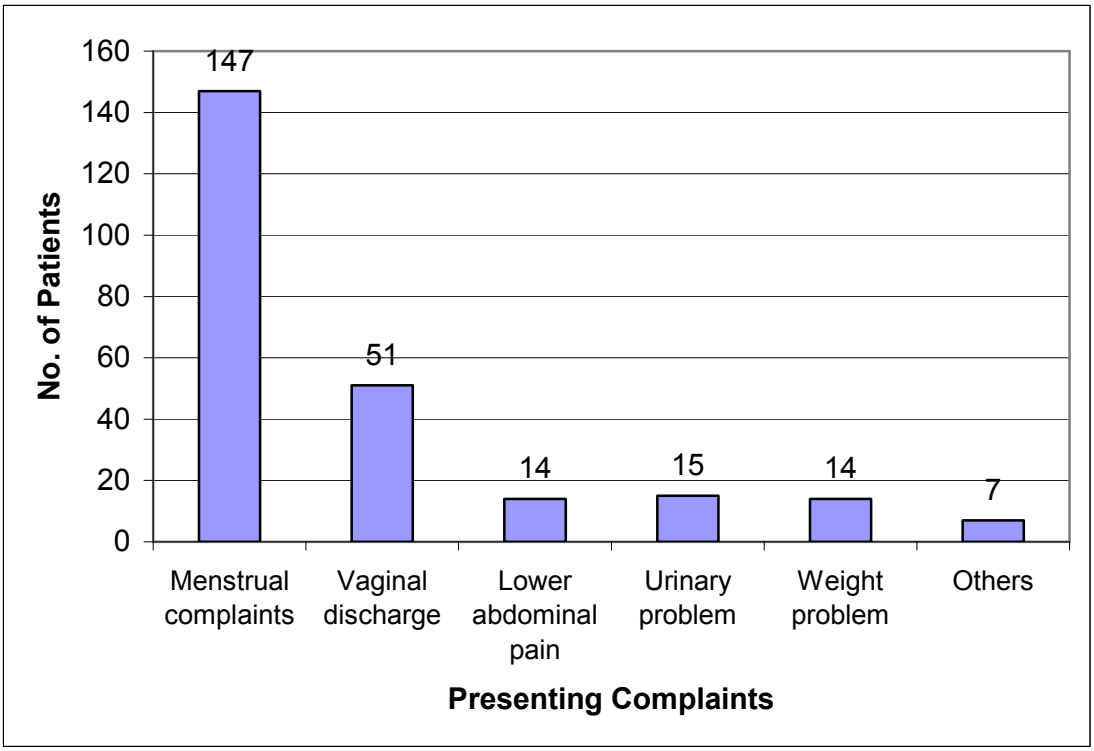
Majority of the adolescent girls under study were anaemic, 25.3% had mild anaemia, 53.3% (maximum) had moderate anaemia and 2.6% suffered from severe anaemia. Only 18.6% of cases were not anaemic as per the Hb% estimation.

Table 7: Presenting complaints in the study population

Complaints	No. of Patients	Percent
Menstrual complaints	147	59.2%
Vaginal discharge	51	20.5%
Lower abdominal pain	14	5.64%
Urinary problem	15	6.04%
Weight problem	14	5.64%
Others	7	2.82%
Total	**248**	**100.0%**

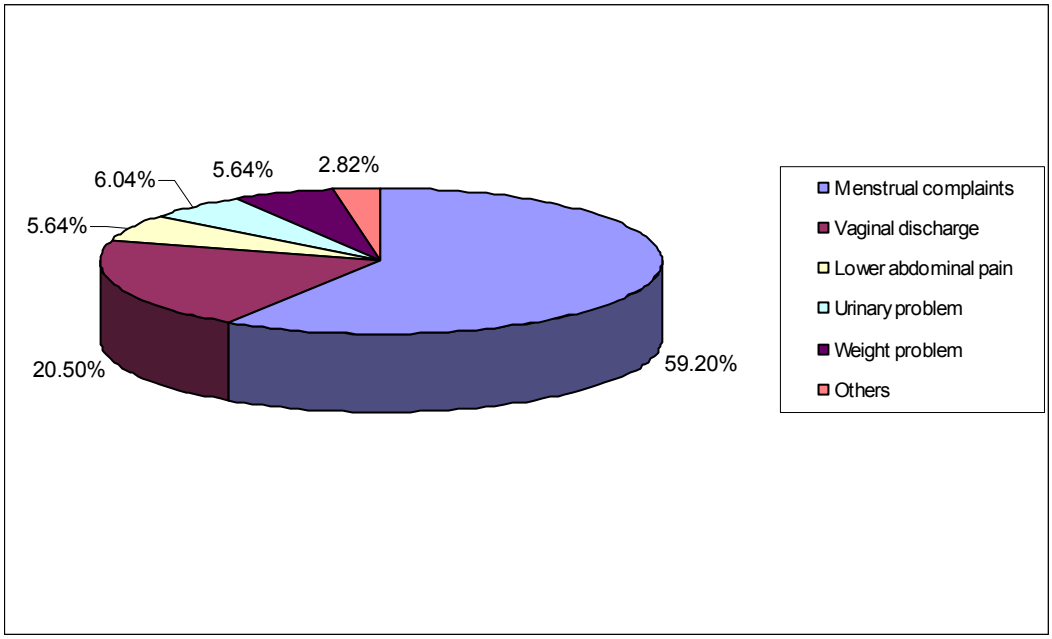
In the present study, various presenting complaints among the adolescent girls were depicted in the table. Most common presenting complaints among the teenage girls was menstrual complaint. Majority of girls were having one or more morbidity.

Chart 7: Presenting complaints in the study population



In the present study, girls were allowed to have multiple responses regarding their presenting complaints. Menstrual complaints the most common complaint (147) among the study group attending the OPD, followed by complaint of white discharge p/v (51).

Chart 7: Presenting complaints in the study population



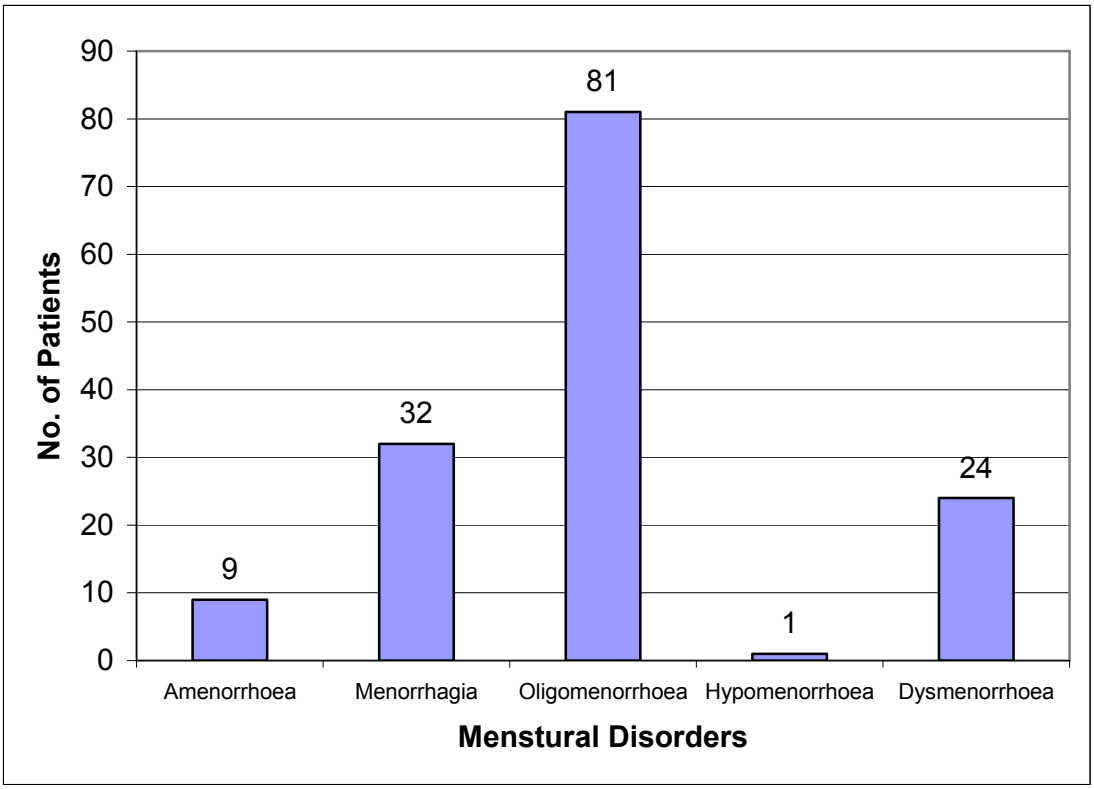
Majority of the girls had menstrual complaints 59.2%, followed by second common complaint was vaginal discharge 20.5% and then followed by urinary tract infection 6.04%.

Table 8 : Types of menstrual dysfunction

Menstrual disorders	No. of patients	Percent
Amenorrhoea	9	6.12
Menorrhagia	32	19.04
Oligomenorrhoea	**81**	**55.1**
Hypomenorrhoea	1	0.68
Dysmenorrhoea	24	16.3
Total	**147**	**100.0**

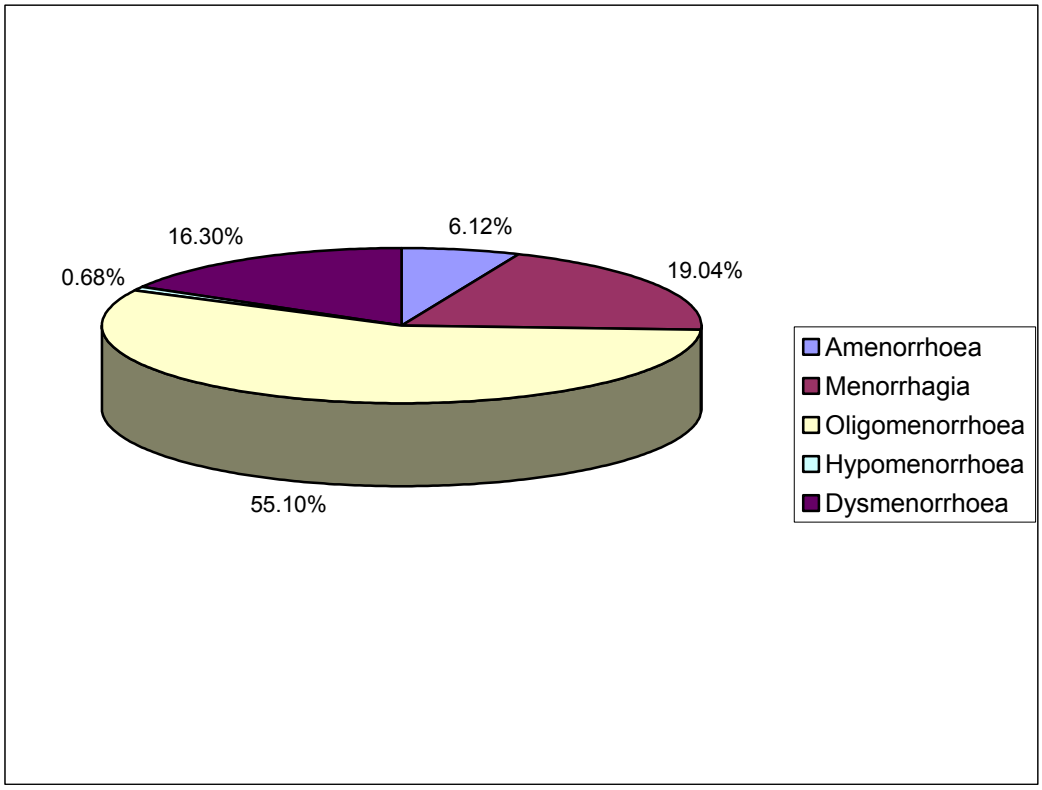
Menstrual complaints being the most common complaints among the studied adolescent group of girls. Menstrual complaints ranged from amenorrhoea to menorrhagia. Dysmenorrhoea was also included in this category.

Chart 8 : Types of menstrual dysfunction



Among the menstrual complaints, the most common type of complaint was that of oligomenorrhoea (81/147), followed by menorrhagia.

Chart 8 : Types of menstrual dysfunction



Majority of girls were suffering from oligomenorrhoea (55.1%) followed by those presenting with menorrhagia (19.04%)

Table 9 : Association between BMI and PCOS among the study group with menstrual complaints.

BMI	No. of patients	Percent	Chi-square Value	P Value
Under Weight	1	3.6%	28.294	0.000
Normal	14	50.0%		
Over Weight	8	28.6%		
Obese	3	10.7%		
Morbid Obesity	2	7.1%		
Total	**28**	**100.00%**		

A highly significant statistical association between BMI and PCOS was seen. Adolescent having higher BMI had increased incidence of PCOS in the USG.

Chart 9 : Association between BMI and PCOS among the study group with menstrual complaints

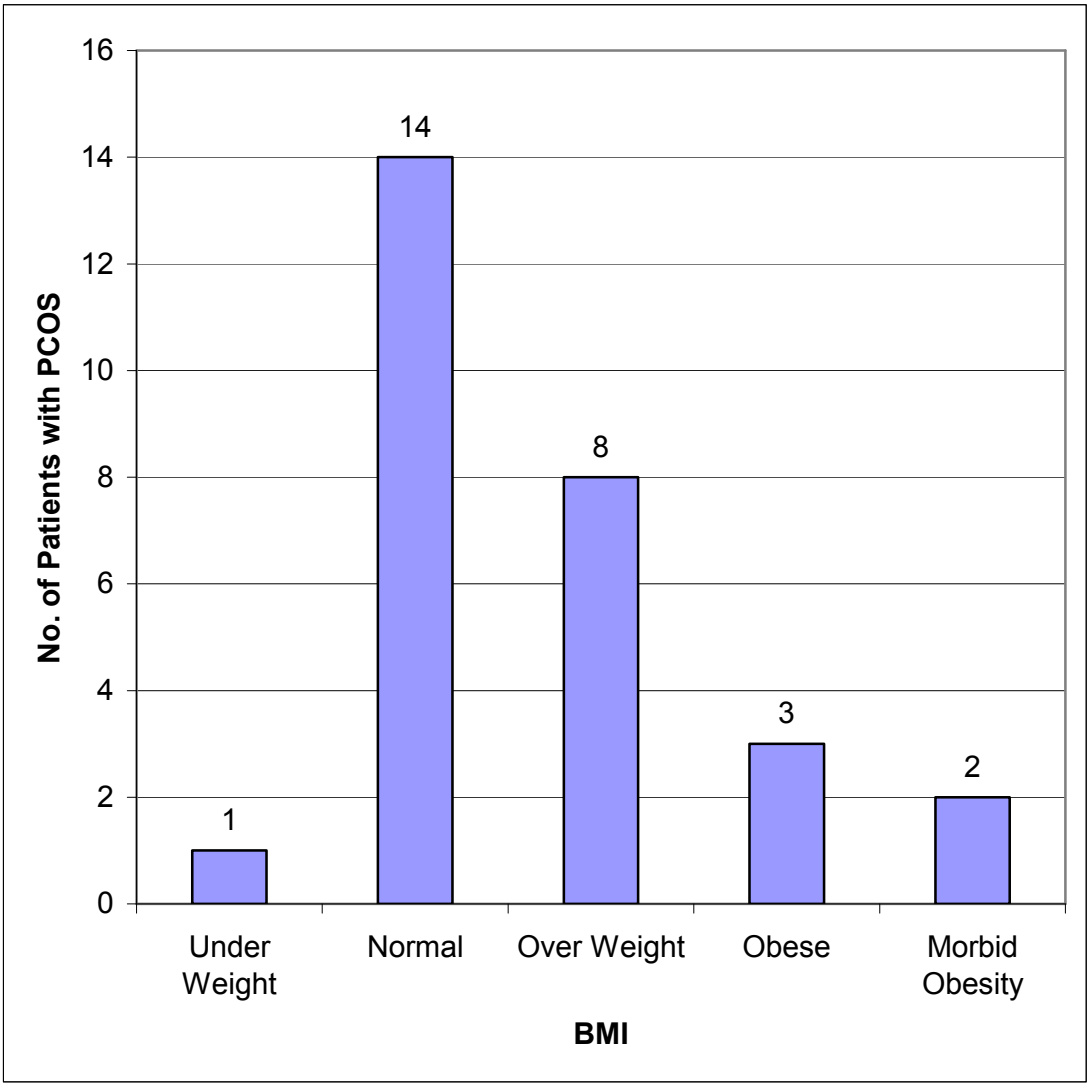


Table 10 : Etiology of Amenorrhoea

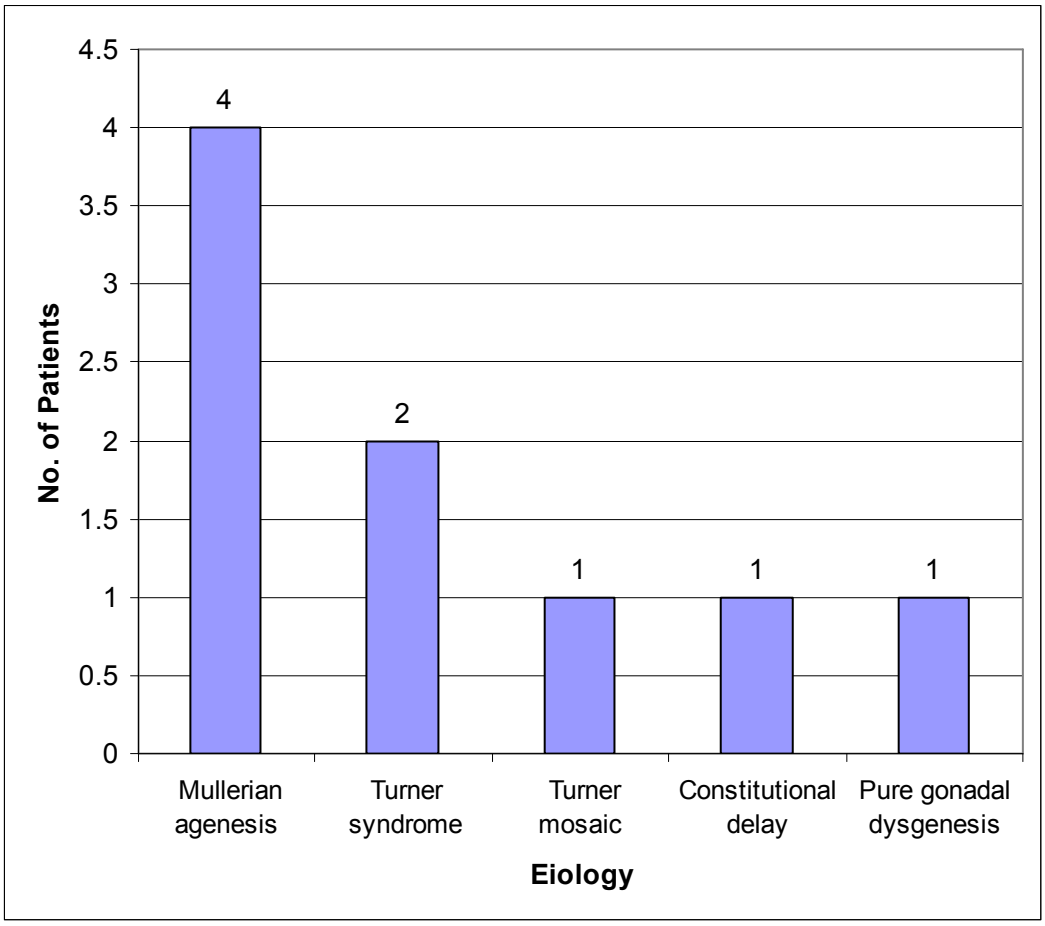
Etiology	Karyotype	No. of patients	Percent
Mullerian agenesis	46 XX	**4**	**44.4**
Turner syndrome	45 X0	2	22.2
Turner mosaic	45 X0 / 46 XX	1	11.1
Constitutional delay	46 XX	1	11.1
Pure gonadal dysgenesis	46 XX	1	11.1
Total		**9**	**100.0**

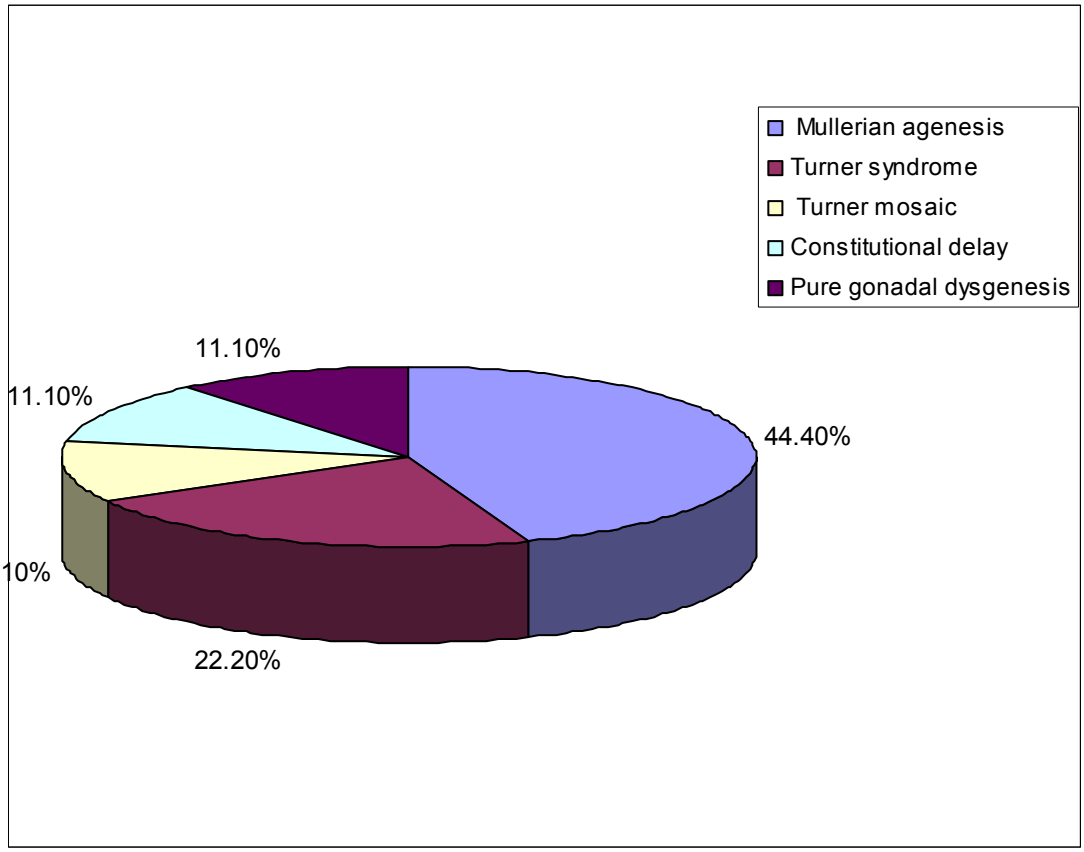
Commonest cause of primary amenorrhoea in this study group were Mullerian agenesis (44.4%).

Chart 10 : Etiology of Amenorrhoea



Out of 9 cases giadnosed with primary amenorrhoea in the study group.the commonest cause was MRKH syndrome.

Chart 10 : Etiology of Amenorrhoea



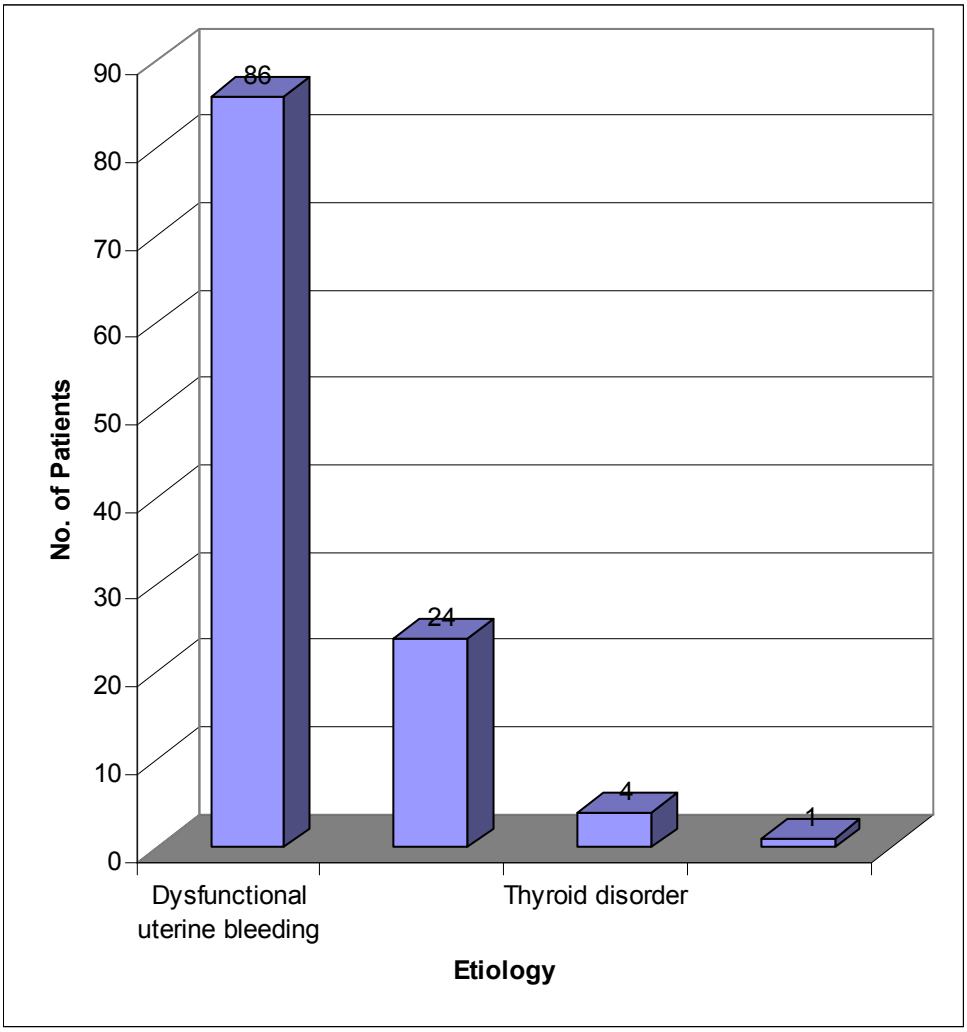
In the present study, maximum percent (44.4%) of cases amenorrhoea was diagnosed with mullerian agenesis, followed by Turner's syndrome (22.2%).

Table 11 : Etiology of Menstrual dysfunctions

Etiology	No. of patients	Percent
Dysfunctional uterine bleeding	**86**	**74.7**
PCOS	24	20.8
Thyroid disorder	4	3.47
Hyperproactinemia	1	0.86
Total	**115**	**100.0**

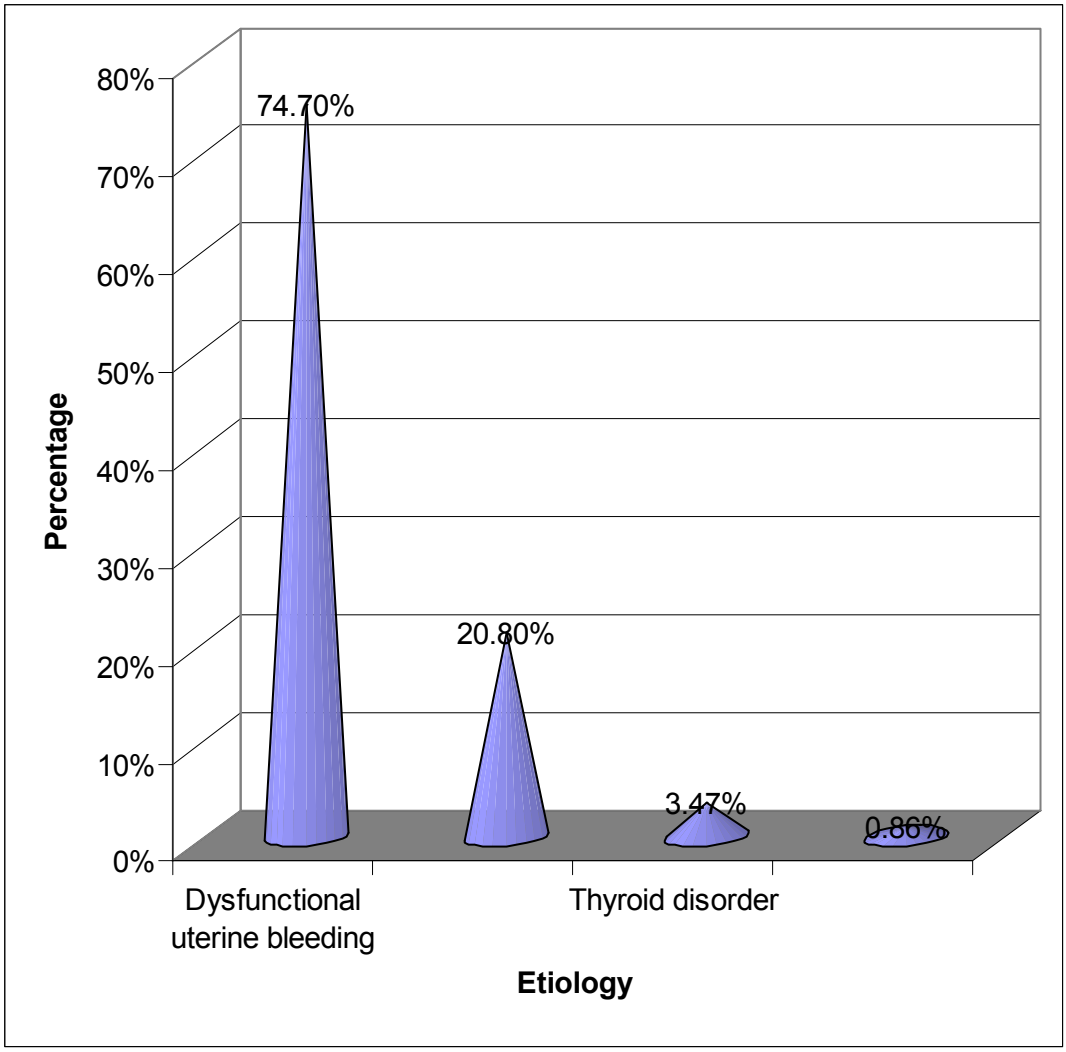
This table shows various causes for the menstrual irregularities in the adolescent girls under study. Most common is the Dysfunctional uterine bleeding.

Table 11 : Etiology of Menstrual dysfunctions



Out of the total 115 case of menstrual dysfunction, 86 cases were due to dysfunctional uterine bleeding without any pelvic pathology followed by PCOS (24) which was the second most common cause for the menstrual disorder in the adolescent age group under study.

Table 11 : Etiology of Menstrual dysfunctions



Commonest cause of menstrual dysfunction in the adolescent girls under study was dysfunctional uterine bleeding without any pelvic pathology (74.4%).

Table 11 : Age in years and dysmenorrhoea in adolescent girls

Age group in years	Total no of cases	No. of cases with dysmenorrhoea
13-15 years	42	6
16-19 years	99	1 8
Total	141	24

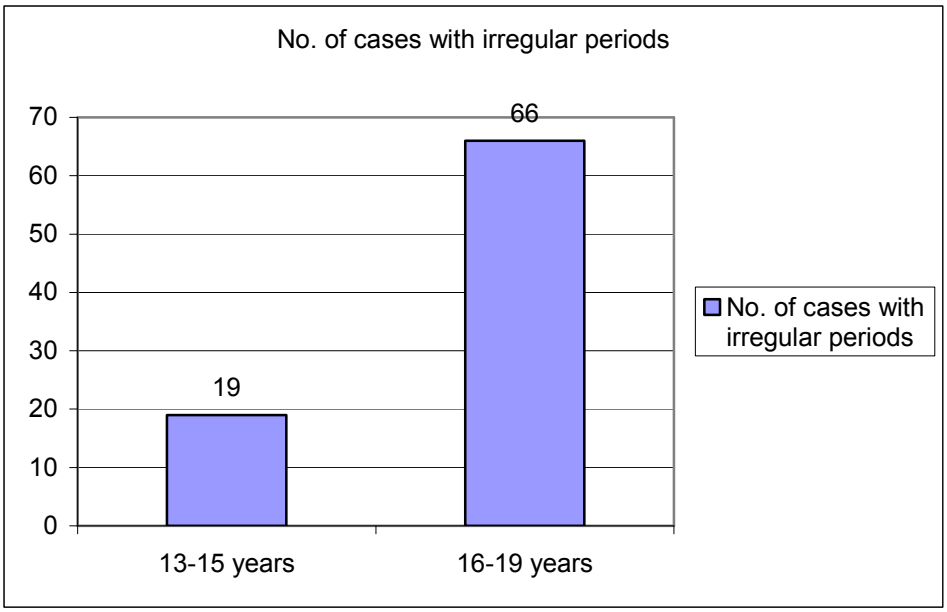
In the present study, the prevalence of dysmenorrhoea is higher in the adolescent girls of age group between 16-19 years.

Table 12 : Age Group in years and Irregular Periods in Adolescent Girls

Age group in years	No. of cases with irregular periods	% within age group in years	% within irregular periods count	Chi square value	P-value
13-15 years	19	45.2%	22.4%	5.656	0.017
16-19 years	66	77.6%	66.7%		

There is a significant statistical association between the age group in years with complain of irregular periods.

Chart 12 : Age in years and irregular menstrual complaints in adolescent girls



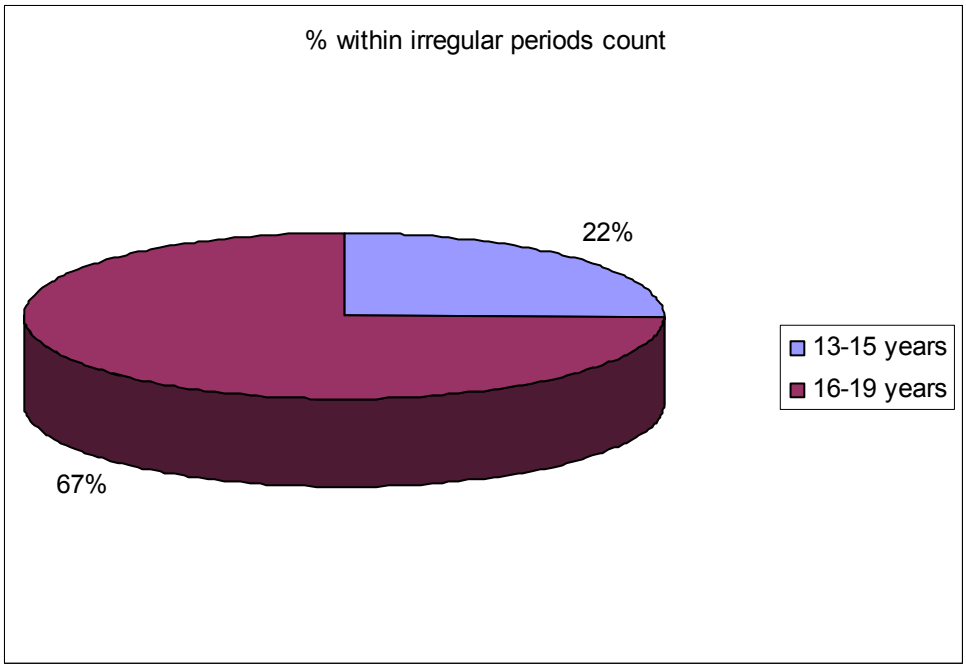


Table 13 : Age in years and Puberty menorrhagia

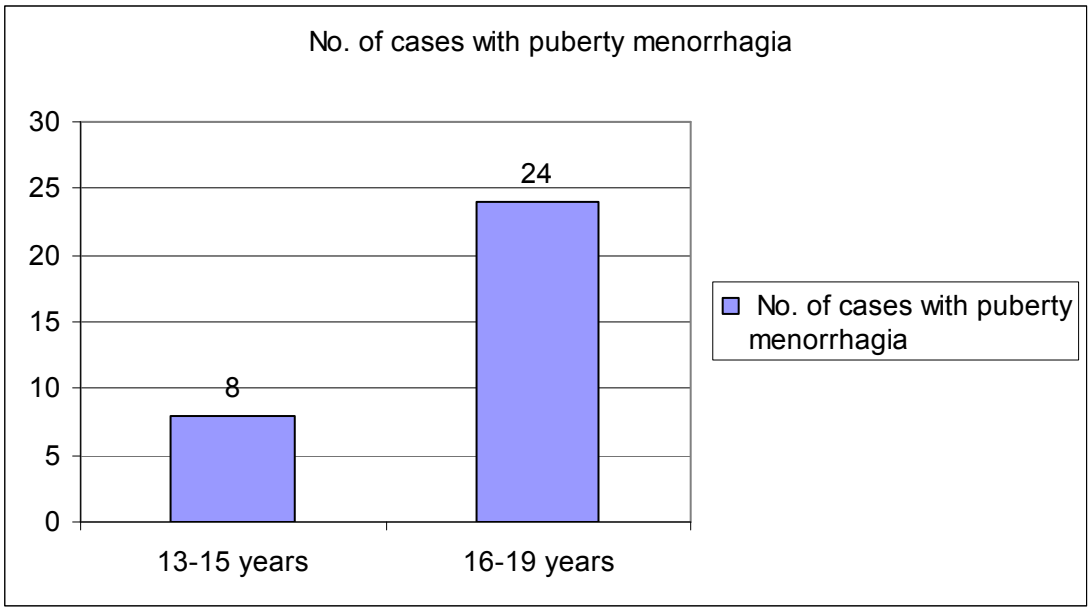
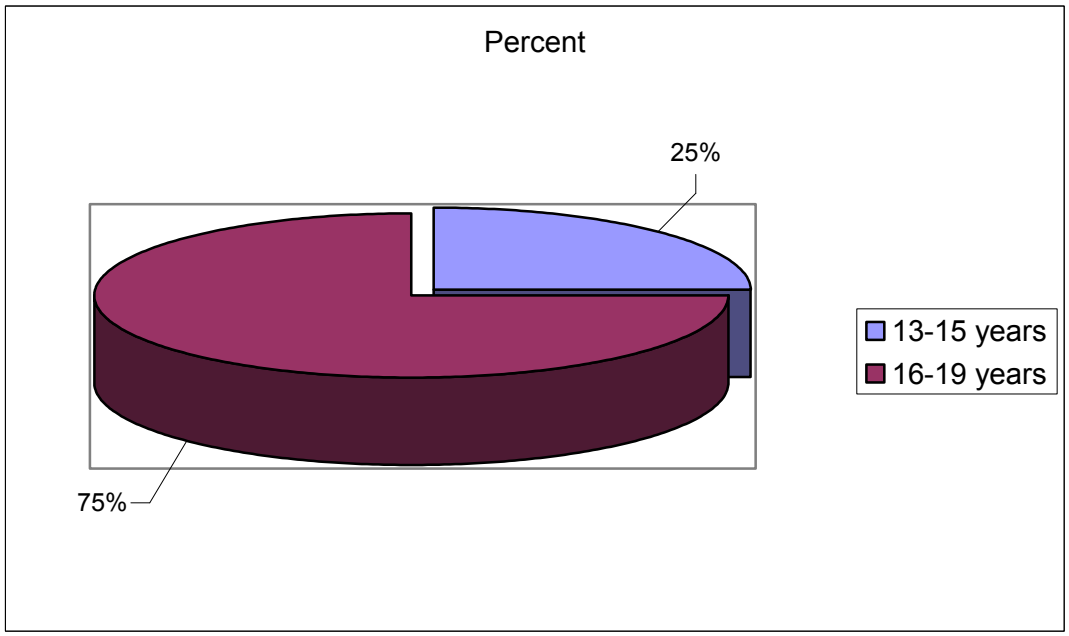
Age group in years	No. of cases with puberty menorrhagia	Percent	Chi square value	P- value
13-14 years	8	25%	8.000	0.005
16-19 years	24	75.0%		
Total	32	100%		

There is a significant statistical association between age group in years and puberty Menorrhagia.

Chart 13 : Age group in years and Puberty menorrhagia in adolescent girls under study.



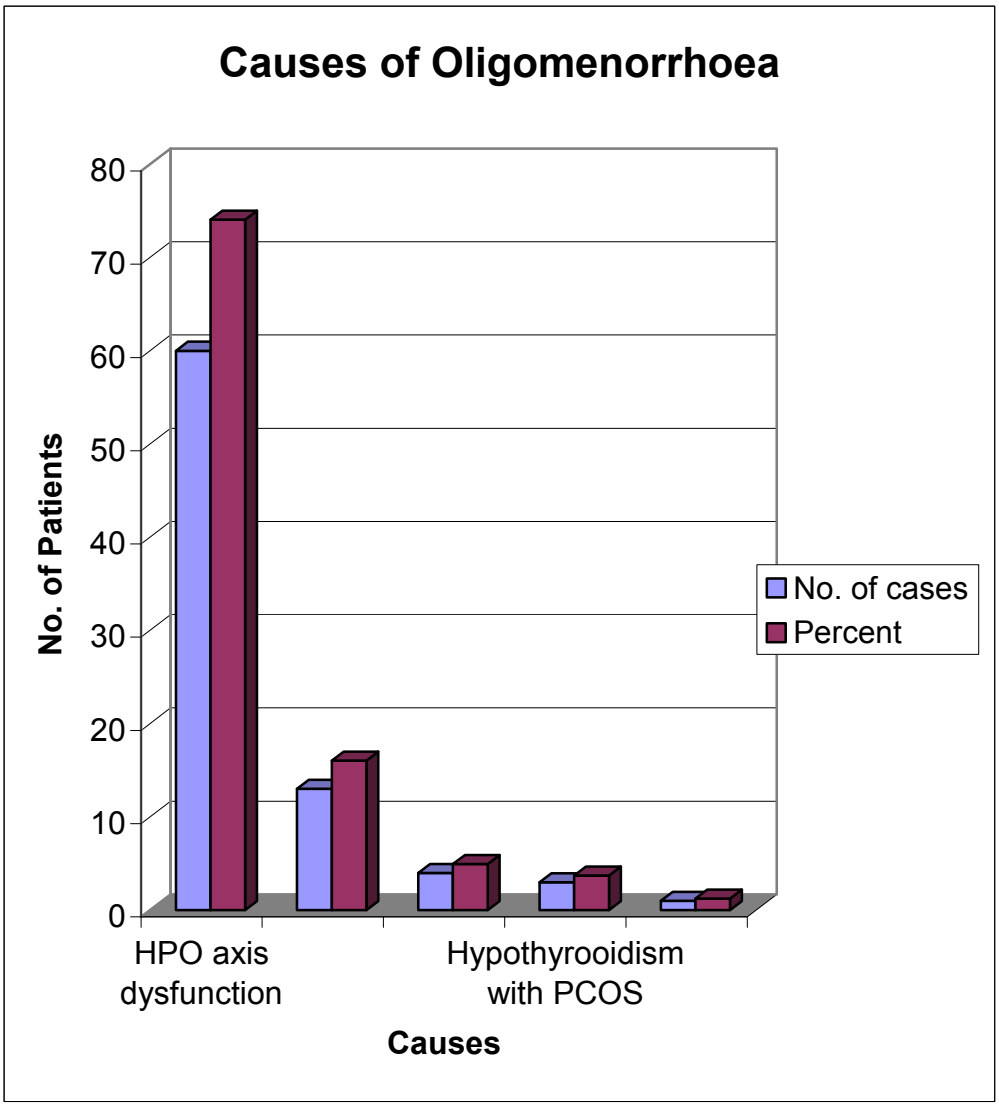


This chart shows that puberty menorrhagia were more common in age group of 16- 19 years i.e; 24 out of all 32cases of puberty menorrhagia.

Table 14 : Causes of oligomenorrhoea

Cause	No. of cases	Percent
HPO axis dysfunction	**60**	**74.07**
PCOS	13	16.04
Hypothyroidism	4	4.93
Hypothyrooidism with PCOS	3	3.70
Hyperprolactinemia	1	1.23
Total	**81**	**100.0**

In the present study 81 cases of oligomenorrhoea were studied. Commonest cause of oligomenorrhoea was HPO axis dysfunction 74.07% , followed by PCOS accounting for 16.04%.



In the present study , the main cause for oligomenorrhoea among the study group of adolescent girls was the immaturity of hypothalamus – pituitary-ovarian axis (74.7%).

Table 15: Association between anaemia and puberty menorrhagia

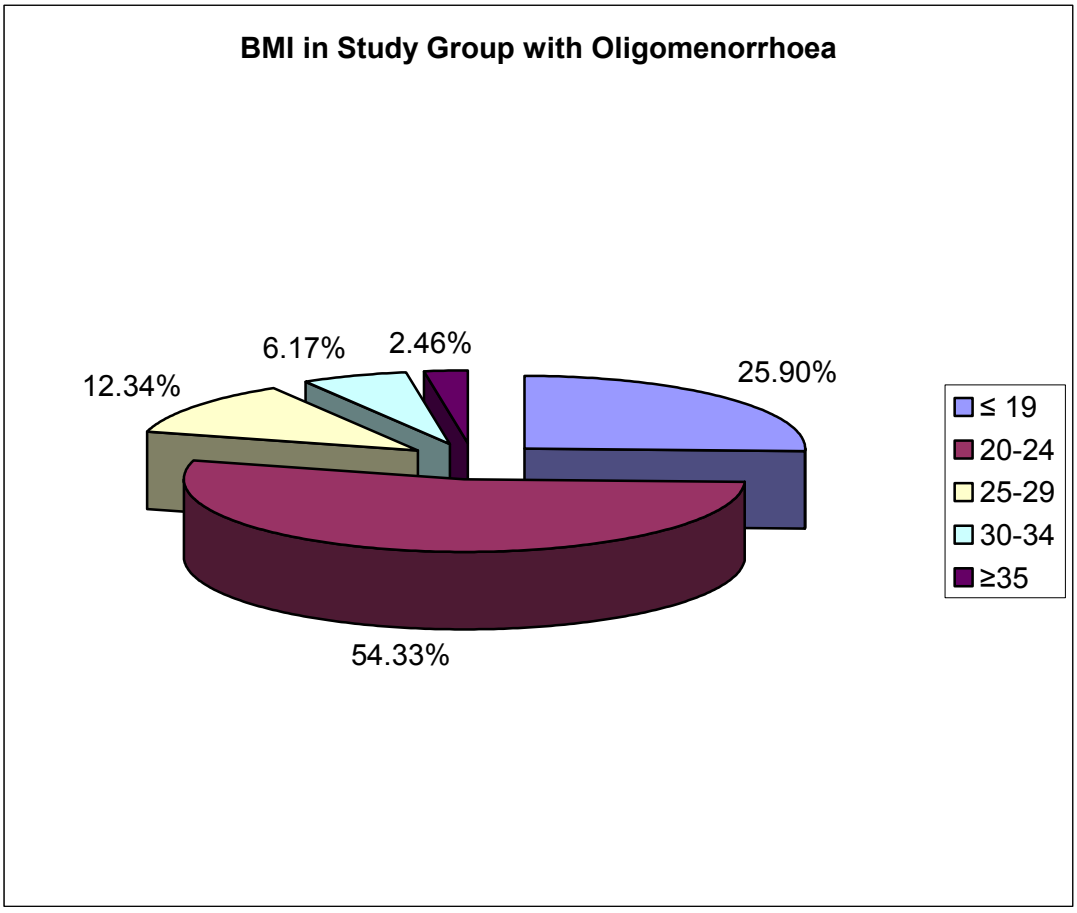
Anaemia	No of cases with menorrhagia	Chi square value	P-value
Normal	1	66.750	0.000
Mild	2		
Moderate	28		
Severe	1		
Total	**32**		

There is highly significant association between the anemia status and the puberty menorrhagia.

Table 16 : BMI in the study group and oligomenorrhoea

BMI	No. of cases	Percent
≤ 19	20	25.9%
20-24	44	54.325%
25-29	10	12.34%
30-34	5	6.17%
≥35	2	2.46%
Total	**81**	**100.0**

Out of 81 cases of oligomenorrhoea 44 cases had normal BMI, 20 were underweight and 17 had BMI higher than the normal.

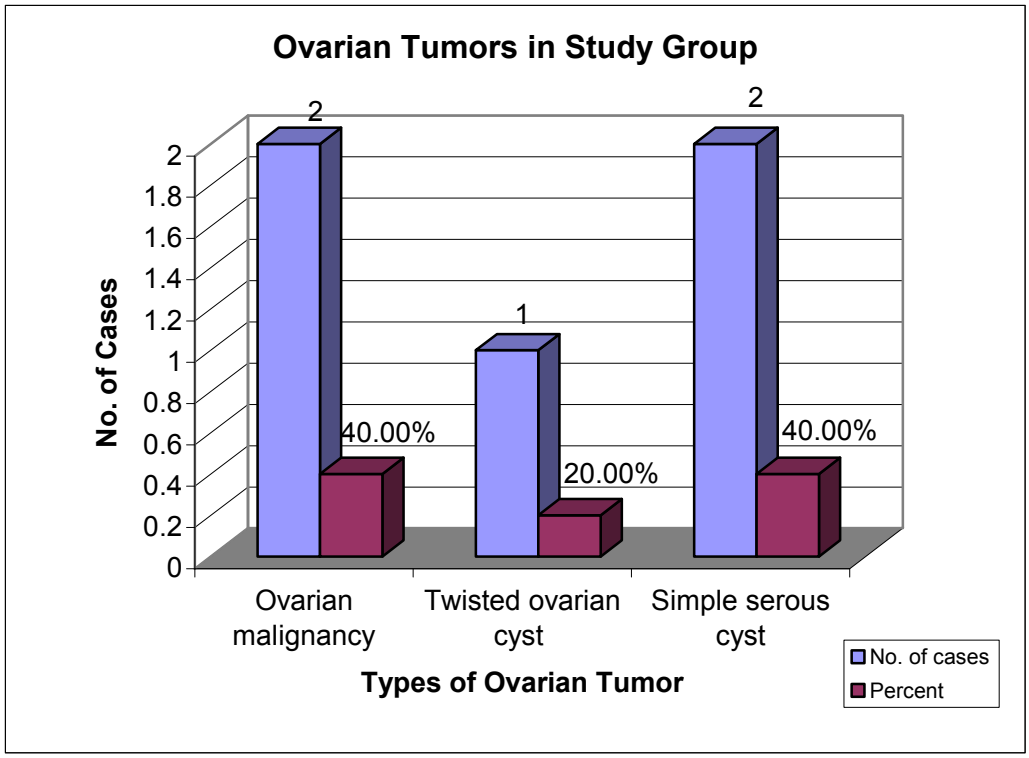


In the present study 54.3% of cases with oligomenorrhoea had normal BMI, 25.9% had were underweight and 20.9% had BMI higher than normal.

Table 15: Ovarian tumors in the study group

Tumors	No. of cases	Percent
Ovarian malignancy	**2**	**40.0%**
Twisted ovarian cyst	**1**	**20.0%**
Simple serous cyst	**2**	**40.0%**
Total	**5**	**100.0%**

In this study, 5 adolescent girls were diagnosed with ovarian tumor (benign or malignant). Most common type of ovarian tumor found in the present study was simple serous ovarian cysts (2/5). Out of the two malignant ovarian tumor, 1 case was of Juvenile granulose cell tumor fig. 1(a) and 1(b) and other was Yolk sac tumor fig.2(a) and 2(b).



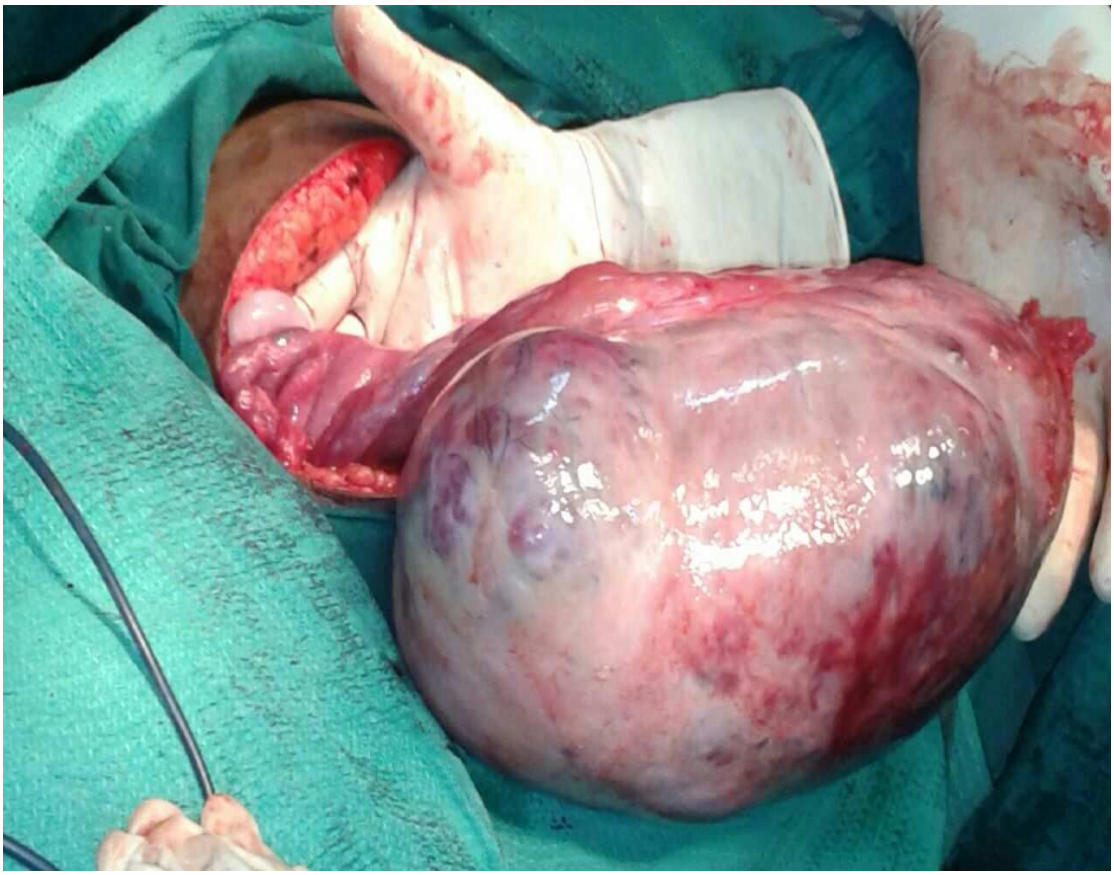


Fig. Gross image of Juvenile Granulosa Cell Tumour of ovary

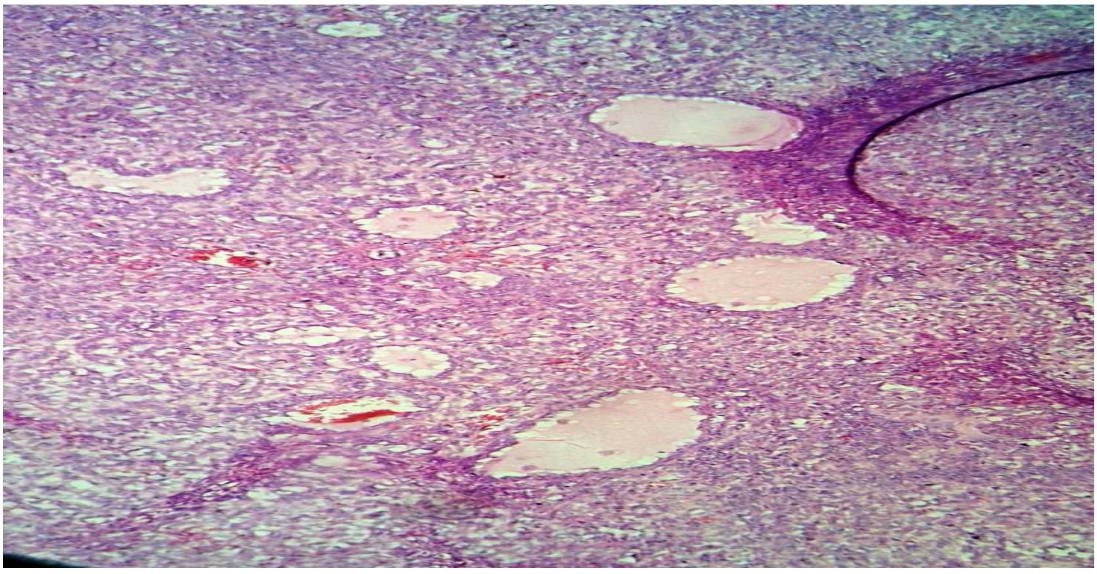

Fig : Microscopic image

Many follicles are lined by cells with atypical ‘ hobnail’ nuclei simulating a tubulocystic clear cell arcinoma

DISCUSSION

This study was conducted at ISO & Government Kasturba Gandhi Hospital for Women & Children to analyse the various gynaecological problems prevalent among the adolescent girls and to know various cause and factors associated with it.

In the present study, maximum incidence of gynaecological problems was seen in the age group of 17 years (23.3%). About 3.33% of girls were school drop outs. Majority of them belonged to family of Class IV socio-economic status and 78.0% came from urban areas.

Disturbances of menstruation, either physiological or pathological, are the most common presenting complaint in adolescent gynaecological clinic. The present study shows that menstrual disorders are the most common gynaecological dysfunction among the adolescent girls(62.3%). These ranges from amenorrhoea to menorrhagia.

1) Primary Amenorrhoea :

In present study amenorrhoea accounted for 4.28% (9/150) of cases, in comparison to that reported by **Sebanti et al (6.45 %) and study by Archana *et al* (6.25%).** Out of the total of 9 cases of Primary amenorrhoea, four cases was found to be of diagnosis Mullerian dysgenesis. Two cases were diagnosed as Turner syndrome. One case underwent vaginoplasty.

Mashchak *et al.*, 1981, Shearman and Roberts *et al.*, 1982, Sebanti *et al.*, 2005 showed that the commonest cause for primary menorrhea was mullerian agenesis (MRKH syndrome).

In the present study, the commonest cause of of primary amenorrhoea with normal secondary sexual characteristics was mullerian agenesis (MRKH syndrome) 33.3%. Common cause of primary amenorrhoea with delayed secondary sexual characteristics were (**Garden *et al.*, 1998, Edmond *et al.*, 1999)**

i) Turner syndrome

ii) Gonadotrophin deficiency

iii) Constitutional delay

In present study, Turner syndrome is the commonest cause of primary amenorrhoea with delayed secondary sexual character.

2) Oligomenorrhoea :

Oligomenorrhoea is the most common menstrual complaint in the present study (57.4%). **Morgan and London *et al.*, 1993** showed that the most common cause of oligomenorrhoea is HPO axis followed by causes like PCOS, stress, thyroid disorder etc. In the present study, HPO axis dysfunction was the most common cause of oligomenorrhoea accounting for 74.04%

Prevalence of menstrual disorders in various studies

Study group	Percent
Balasubramanian *et al* , 2000	26.62%
Goswami *et al* , 2005	58.8%
Kulkarni *et al* , 2011	11.16%
Present study	55.1%

PCOS (20.8%) is the second most common cause of oligomenorrhoea followed by hypothyroidism (3.47%). PCOS which was diagnosed based on the clinical criteria of menstrual dysfunction, hyperandrogenism and ultrasonographic findings.

There were 14/24 cases of PCOS who presented with complain of oligomenorrhoea and 10 cases presented with menorrhagia. PCOS is the cause of menstrual irregularities in 24/114 (21.0%) cases in the present study which is comparable to the finding of 22.9% in the study conducted by **Archana *et al* (2013).**

In the present study, the most least common cause of menstrual irregularities is polymenorrhoea (0.9%).

3) Puberty menorrhagia :

Puberty menorrhagia accounts for 19.8% of all menstrual complains in the present study. 10 out of 28 cases were admitted in our hospital and 4 cases had severe anaemia and 2 moderate anaemia, which required blood transfusion.

Most of cases of puberty menorrhagia had anaemia ranging from mild to severe, predominantly anemia ranging from haemoglobin percentage of 8.1- 10.9 gm%. Anaemic patients were treated with haematinics both oral and parenteral preparation, hormones and blood transfusion wherever indicated.

4) **Dysmenorrhoea :**

Primary dysmenorrhoea was presenting complaint in 10 cases out of total 18 girls in the present study group. In rest of 8 cases, dysmenorrhoea was an associated complain with other complains of menstrual irregularities .3 out of 10 cases had problem severe enough to prevent them from going to school. These girls on detailed history elicitation, their mother and sibling also had similar history of severe dysmenorrhoea. **Dickens *et al.,*** also mentioned family history of primary dysmenorrhoea.

Prevalence of dysmenorrhoea was high in late adolescent age group. **Balasubramanian *et al.*, 2000 and Rehman *et al* .,2004** also reported similar study findings.

5) Leucorrhoea :

In this study, 51 cases (21.07%) of vaginal discharge was the second most commonest complaint in the adolescent girls. Most of them had physiological leucorrhoea which responded to counseling and maintenance of personal hygiene.

6) Ovarian tumor :

Ovarian tumor were found in 5/150 cases (3.3%) . Out of these 2 had simple serous cysts and 1 with twisted ovarian cyst. There were 2 cases of malignant ovarian tumour which turned out to be a case of Juvenile granulosa cell tumor and Yolk sac tumor confirmed by histopathological studies. **Sebanti *et al.,* 2005** and **Archana *et al.,* 2013** have reported a higher incidence of ovarian tumor in their series, 15.3% and 4.5% respectively.

Study group	**Incidence %**
Oumachigui *et al.*	6%
Dhamne *et al.*	2.25%
Huggmen *et al.*	1%
Sebanti *et al.*	15.3%
Archana *et al.*	4.5%
Present study	3.3%

Two cases in the study presented with bartholin cyst, out of which one case was of recurrent bartholin cysts turning to bartholin abscess,was treated by drainage and antibiotic. Another case presented with injury to perineum, due to sexual assault.

SUMMARY

- Low socio economic group coming from urban population was the maximum group of girls studied.
- Maximum incidence of gynaecological problems was seen in the age group of 17 years.
- Among the various presenting complaints in studied adolescent girls, menstrual irregularities were the most common.
- Oligomenorrhoea was the most common menstrual problem in this study.
- Anovulation is the most common cause of menorrrhagia in adolescents.
- Majority of teenage (81.2%) suffered from anemia ranging from mild to severe types of anaemia.
- 21.42% patients with puberty menorrhagia received blood transfusion.
- The most commonest cause of oligomenorrhoea was the Hypothalamic -pituitary – gonadal axis dysfunction.

- Counseling and reassurance was an integral part of treatment strategies.
- PCOS and hypothyroidism were the other endocrinological abnormalities common among the adolescent girls.
- Dysmenorrhoea was more common among the late adolescent age group.
- Leucorrhoea in adolescent girls in the present study were most commonly physiological, counseled and explained to maintain proper hygiene.
- MRKH Syndrome (Mullerian agenesis) is the commonest cause of primary amenorrhoea.
- A combined effort of team comprising gynaecologist, endocrinologist, genetist is required in arriving the final diagnosis of in cases of primary amenorrhoea.
- In the present study benign ovarian tumor were more common than malignant ovarian tumor.

CONCLUSION

Adolescent gynaecology is an important sub- specialized part of gynaecology. The importance of the reproductive health problems among the adolescent has emerged tremendously during recent years.

Endocrinal abnormalities like PCOS are associated with future reproductive as well as metabolic morbidity. Therefore, it is very important to evaluate and manage endocrinal abnormalities in adolescent properly so as to secure a healthy reproductive life.

Menorrhagia, at all stages of life severely affects the quality of life. Effective management of puberty menorrhagia is mandatory in order to avoid adolescent with anaemia. As mentioned earlier, adolescent girls being the direct reproducer of future generation, it is important to avoid adolescent embarking on pregnancy with anaemia, which in long run reduce perinatal and maternal morbidity and mortality.

Teenage problems need to be dealt with utmost sensitivity. Counseling teenage girls as well as parents is an integral part of the treatment strategies. Awareness regarding health, nutrition and hygiene should be included in the counseling in order to curtail problems like anemia, leucorrhoea.

Though, adolescent gynaecology is not a new subject. But, it still needs greater attention and increased awareness, in order to protect and promote the health of adolescents. As the problems are specific to this age group, setting up of a separate ‘Adolescent Gynaecological Clinics’ is the need of the hour.

INFORMATION SHEET

- We are conducting a study on "**STUDY ON ADOLESCENT GYNAECOLOGICAL PROBLEMS**" among patients attending Kasturba Gandhi Government Hospital Chennai and for that your clinical details may be valuable to us.
- We are selecting certain patients and if you are found eligible, we may be using your clinical details in such a way so as to not affect your final report or management.
- The privacy of the patients in the research will be maintained throughout the study. In the event of any publication or presentation resulting from the research, no personally identifiable information will be shared.
- Taking part in this study is voluntary. You are free to decide whether to participate in this study or to withdraw at any time; your decision will not result in any loss of benefits to which you are otherwise entitled.
- The results of the special study may be intimated to you at the end of the study period or during the study if anything is found abnormal which may aid in the management or treatment.

CERTIFICATE OF APPROVAL

To

Dr.Radhe Akang,
Postgraduate in Obstetrics & Gynaecology,
Kasthurba Gandhi Govt. General Hospital,
Madras Medical College, Chennai-5.

Dear **Dr.Radhe Akang,**

The Institutional Ethics Committee of Madras Medical College, reviewed and discussed your application for approval of the proposal entitled "**Study on Adolescent Gynaecological Problems**" No.29032014.

The following members of Ethics Committee were present in the meeting held on 11.03.2014 conducted at Madras Medical College, Chennai-3.

1.	Dr. C.Rajendran, M.D,	-- Chairperson
2.	Dr.R.Vimala, MD., Dean, MMC, Ch-3.	-- Deputy Chairperson
3.	Prof. Kalaiselvi, M.D, Vice Principal, MMC, Ch-3	-- Member Secretary
4.	Prof. Nandhini, M.D, Inst. of Pharmacology, MMC, Ch-3	-- Member
5.	Prof.Bhavani Sankar, M.S, Prof & HOD General Surgery, MMC, Ch-3	-- Member
6.	Prof.V.Padmavathi, M.D, I/c. Director of Pathology, MMC, Ch-3	-- Member
7.	Thiru. S. Govindasamy, BA., BL	-- Lawyer
8.	Tmt.Arnold Saulina, MA MSW	-- Social Scientist
9.	Thiru.S.Ramesh Kumar, Administrative Officer, MMC, Ch-3.	-- Lay Person

We approve the proposal to be conducted in its presented form.

Sd/Chairman & Other Members

The Institutional Ethics Committee expects to be informed about the progress of the study, and SAE occurring in the course of the study, any changes in the protocol and patients information / informed consent and asks to be provided a copy of the final report.

INTRODUCTION
Puberty is coined from latin word 'Pubertus' meaning 'grown up' (Foster 1992). "Puberty is the period of physiological changes in secondary sexual characteristics development and their attainment of capability of sexual reproduction". Puberty not only deals with mere physiological changes but there is also tremendous psychological and emotional changes in the life of the adolescent. Adolescence, in simple words is nothing but the phase of life during which a carefree child becomes the responsible adult.
"WHO defines adolescence as the period in human growth and development that occurs after childhood and before adulthood, from age 10-19 years". It is an ongoing process i.e; the psychological and physiological changes which occur may begin before and even can continue after this age(Progress in Obstetrics and Gynaecology, vol 12; John Studd).
The biological determinant of adolescence are universal, however

1. Age Group in years
   - 1 → 13 – 15 years
   - 2 → 16 – 19 years

2. Socio economic Status
   - 3 → Class III
   - 4 → Class IV
   - 5 → Class V

3. Educational status
   - 1 → Primary
   - 2 → Secondary
   - 3 → Higher Secondary

4. Localities
   - 1 → Urban
   - 2 → Rural

5. Body Mass Index (BMI)
   - 1 → ≤ 19 (Under weight)
   - 2 → 20 – 24 (Normal)
   - 3 → 25 – 29 (over weight)
   - 4 → 30 – 34 (Obese)
   - 5 → ≥ 35 (Morbid obesity)

6. Complaints
   - 1 - Irregular Periods
   - 2 - Scanty Periods
   - 3 - Profuse prolonged bleedings P/v
   - 4 - White discharge p/v
   - 5 - lower abdominal pain
   - 6 - Excessive weight gain
   - 7 - increased hair growth over face
   - 8 - Neck swelling
   - 9 - Dysmenorrhoea

7. Goitre
   - 1 - Present
   - 2 - Absent

8. Hirsution
   - 1 → Present
   - 2 → Absent

9. Hb%
   - 1 → Normal (≥ 12 gm %)
   - 2 → Mild (11.0 - 11.0 gm %)
   - 3 → Moderate (8.1 – 10.9)
   - 4 → Severe (< 9 gm %)

10. USG
    - 0 → Not done
    - 1 → Normal
    - 2 → PCOS
    - 3 → T.O. Mass

11. TSH
    - 1 → Normal
    - 2 → High

12. PL
    - 1 → Normal
    - 2 → Not done
    - 0 → High

13. LH
    - 1 → Normal
    - 2 → High

14. Diagnosis
    - 1 → Oligomenorrhoea
